TMP468

SBOS762 – NOVEMBER 2016

TMP468 9-Channel (8-Remote and 1-Local), High-Accuracy Temperature Sensor

1 Features

- 8-Channel Remote Diode Temperature Sensor Accuracy: ±0.75°C
- Local Temperature Sensor Accuracy: ±0.35°C
- Temperature Resolution: 0.0625°C
- Supply and Logic Voltage Range: 1.7 V to 3.6 V
- 67-µA Operating Current (1 SPS, All Channels Active)
- 0.3-µA Shutdown Current
- Remote Diode: Series Resistance Cancellation, η-Factor Correction, Offset Correction, and Diode Fault Detection
- Register Lock Function Secures Key Registers
- I²C- or SMBus™-Compatible Two-Wire Interface With Pin-Programmable Address
- 16-Bump DSBGA Package

2 Applications

- MCU, GPU, ASIC, FPGA, DSP, and CPU Temperature Monitoring
- Telecommunication Equipment
- Servers and Personal Computers
- Cloud Ethernet Switches
- Secure Data Centers
- Highly Integrated Medical Systems
- Precision Instruments and Test Equipment
- LED Lighting Thermal Control

3 Description

The TMP468 device is a multi-zone, high-accuracy, low-power temperature sensor using a 2-wire, SMBus- or I²C-compatible interface. Up to eight remote diode-connected temperature zones can be monitored simultaneously in addition to the local temperature. Aggregating the temperature measurements across a system allow improved performance through tighter guard bands and can also reduce board complexity. A typical use case is for monitoring the temperature across different processors, such as MCUs, GPUs, and FPGAs in complex systems such as servers and telecommunications equipment.

Advanced features such as series resistance cancellation, programmable non-ideality factor, programmable offset, and programmable temperature limits are included to provide a robust thermal monitoring solution with improved accuracy and noise immunity.

Each of the 8 remote channels (and the local channel) can be programmed independently with two thresholds which trigger when the corresponding temperature is exceeded at the measured location. In addition, there is a programmable hysteresis setting to avoid constant toggling of the threshold.

Device Information[1]

PART NUMBER	PACKAGE	BODY SIZE (NOM)
TMP468	DSBGA (16)	1.60 mm × 1.60 mm

(1) For all available packages, see the orderable addendum at the end of the data sheet.

Typical Application
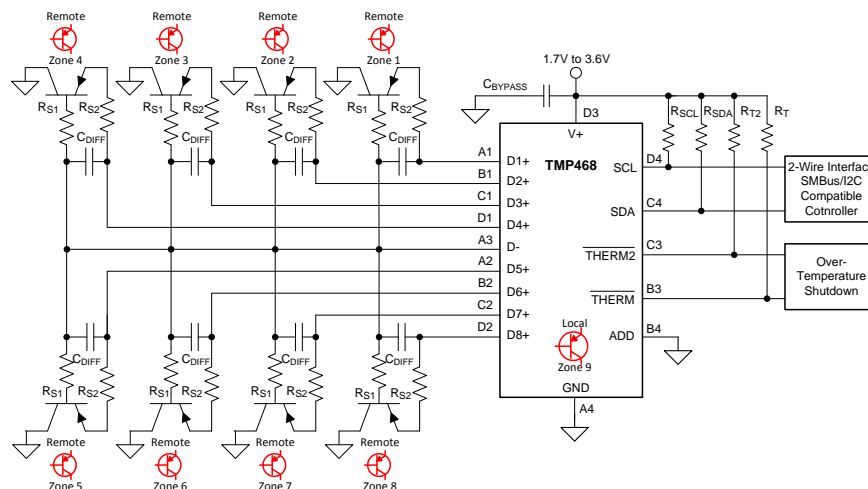

Note: See section *Design Requirements* for remote diode recommendations (most common discrete transistor recommendation is MMBT3904). Place remote diode differential filter capacitors close to TMP468 pins. Unused diode channels must be tied to D−. Remote diode filter capacitor and the sum of the series resistance (R_{S1} + R_{S2}) values must be less than 1 nF and 1 kΩ, respectively.

5 Description (continued)

The TMP468 provides very high accuracy (0.75°C) and very high resolution (0.0625°C) measurement capabilities. It also supports low voltage rails (1.7 V to 3.6 V), common 2-wire interfaces, and is available in a small, space efficient package (1.60 mm × 1.60 mm) for easy integration into computing systems. Temperature ranges of –55°C to 150°C are supported.

Pin Functions

PIN		TYPE	DESCRIPTION
NAME	NO.		
ADD	B4	Digital input	Address select. Connect to GND, V+, SDA, or SCL.
D1+	A1	Analog inputs	Positive connection to remote temperature sensors. A total of 8 remote channels are supported. An unused channel must be connected to D–.
D2+	B1		
D3+	C1		
D4+	D1		
D5+	A2		
D6+	B2		
D7+	C2		
D8+	D2		
D–	A3	Analog input	Negative connection to remote temperature sensors. Common for 8 remote channels.
GND	A4	Ground	Supply ground connection
SCL	D4	Digital input	Serial clock line for I2C- or SMBus-Compatible Two-Wire interface. Input; requires a pullup resistor to a voltage between 1.7 V and 3.6 V (not necessarily V+) if driven by an open-drain output.
SDA	C4	Bidirectional digital input-output	Serial data line for I2C- or SMBus-Compatible Two-Wire interface. Open-drain; requires a pullup resistor to a voltage between 1.7 V and 3.6 V, not necessarily V+.
$\overline{\text{THERM}}$	B3	Digital output	Thermal shutdown or fan-control pin. Active low; open-drain; requires a pullup resistor to a voltage between 1.7 V and 3.6 V, not necessarily V+. If this pin is not used it may be left open or grounded.
$\overline{\text{THERM2}}$	C3	Digital output	Second $\overline{\text{THERM}}$ output. Active low; open-drain; requires a pullup resistor to a voltage between 1.7 V and 3.6 V, not necessarily V+. If this pin is not used it may be left open or grounded.
V+	D3	Power supply	Positive supply voltage, 1.7 V to 3.6 V; requires 0.1-µF bypass capacitor to ground.

7 Specifications

7.1 Absolute Maximum Ratings

over operating free-air temperature range (unless otherwise noted)[1]

		MIN	MAX	UNIT
Power supply	V+	−0.3	6	V
Input voltage	$\overline{THERM}$, $\overline{THERM2}$, SDA, SCL and ADD only	−0.3	6	V
	D+1 through D+8	−0.3	((V+) + 0.3) and ≤ 6	
	D- only	−0.3	0.3	
Input current	SDA Sink	−25		mA
	All other pins	−10	10	
Operating temperature		−55	150	°C
Junction temperature (T_J max)			150	°C
Storage temperature, T_{stg}		−60	150	°C

(1) Stresses beyond those listed under *Absolute Maximum Ratings* may cause permanent damage to the device. These are stress ratings only, which do not imply functional operation of the device at these or any other conditions beyond those indicated under *Recommended Operating Conditions*. Exposure to absolute-maximum-rated conditions for extended periods may affect device reliability.

7.2 ESD Ratings

			VALUE	UNIT
$V_{(ESD)}$	Electrostatic discharge	Human body model (HBM), per ANSI/ESDA/JEDEC JS-001[1]	±2000	V
		Charged device model (CDM), JEDEC specification JESD22-C101[2]	±750	

(1) JEDEC document JEP155 states that 500-V HBM allows safe manufacturing with a standard ESD control process.
(2) JEDEC document JEP157 states that 250-V CDM allows safe manufacturing with a standard ESD control process.

7.3 Recommended Operating Conditions

over operating free-air temperature range (unless otherwise noted)

		MIN	NOM	MAX	UNIT
V+	Supply voltage	1.7		3.6	V
T_A	Operating free-air temperature	−40		125	°C

7.4 Thermal Information

THERMAL METRIC[1]		TMP468 YFF (DSBGA) 16 PINS	UNIT
$R_{\theta JA}$	Junction-to-ambient thermal resistance	76	°C/W
$R_{\theta JC(top)}$	Junction-to-case (top) thermal resistance	0.7	°C/W
$R_{\theta JB}$	Junction-to-board thermal resistance	13	°C/W
ψ_{JT}	Junction-to-top characterization parameter	0.4	°C/W
ψ_{JB}	Junction-to-board characterization parameter	13	°C/W

(1) For more information about traditional and new thermal metrics, see the *Semiconductor and IC Package Thermal Metrics* application report.

7.5 Electrical Characteristics

At T_A = –40°C to 125°C and V+ = 1.7 V to 3.6 V, unless otherwise noted.

PARAMETER		CONDITIONS		MIN	TYP	MAX	UNIT
TEMPERATURE MEASUREMENT							
T_{LOCAL}	Local temperature sensor accuracy	T_A = 20°C to 30°C, V+ = 1.7 V to 2 V		–0.35	±0.125	0.35	°C
		T_A = –40°C to 125°C, V+ = 1.7 V to 2.0 V		–0.75	±0.125	0.75	
		T_A = –40°C to 125°C, V+ = 1.7 V to 3.6 V		–1	±0.5	1	
T_{REMOTE}	Remote temperature sensor accuracy	T_A = –10°C to 50°C, T_D = –55°C to 150°C, V+ = 1.7 V to 3.6 V		–0.75	±0.125	0.75	°C
		T_A = –40°C to 125°C, T_D = –55°C to 150°C, V+ = 1.7 V to 3.6 V		–1	±0.5	1	
	Local temperature error supply sensitivity	V+ = 1.7 V to 3.6 V		–0.15	±0.05	0.15	°C/V
	Remote temperature error supply sensitivity	V+ = 1.7 V to 3.6 V		–0.25	±0.1	0.25	°C/V
	Temperature resolution (local and remote)				0.0625		°C
	ADC conversion time	One-shot mode, per channel (local or remote)			16	17	ms

	Hysteresis				200		mV
	SDA output-low sink current			20			mA
V_{OL}	Low-level output voltage	I_O = –20 mA; V+ ≥ 2 V			0.15	0.4	V
		I_O = –15 mA; V+ < 2 V				0.2 × V+	V
	Serial bus input leakage current	0 V ≤ V_{IN} ≤ 3.6 V		–1		1	µA
	Serial bus input capacitance				4		pF
DIGITAL INPUTS (ADD)							
V_{IH}	High-level input voltage			0.7 × (V+)			V
V_{IL}	Low-level input voltage			–0.3		0.3 × (V+)	V
	Input leakage current	0 V ≤ V_{IN} ≤ 3.6 V		–1		1	µA
	Input capacitance				4		pF
DIGITAL OUTPUTS ($\overline{THERM}$, $\overline{THERM2}$)							
	Output-low sink current	V_{OL} = 0.4 V		6			mA
V_{OL}	Low-level output voltage	I_O = –6 mA			0.15	0.4	V
I_{OH}	High-level output leakage current	V_O = V+				1	µA
POWER SUPPLY							
V+	Specified supply voltage range			1.7		3.6	V
I_Q	Quiescent current	Active conversion, local sensor			240	375	µA
		Active conversion, remote sensors			400	600	
		Standby mode (between conversions)			15	21	
		Shutdown mode, serial bus inactive			0.3	4	
		Shutdown mode, serial bus active, f_S = 400 kHz			120		
		Shutdown mode, serial bus active, f_S = 2.56 MHz			300		
POR	Power-on-reset threshold	Rising edge			1.5	1.65	V
		Falling edge		1	1.2	1.35	
POH	Power-on-reset hysteresis				0.2		V

7.6 Two-Wire Timing Requirements

At T_A = –40°C to 125°C and V+ = 1.7 V to 3.6 V, unless otherwise noted. With master and slave at same V+. Values are based on statistical analysis of samples tested during initial release.

		FAST-MODE		HIGH-SPEED MODE		
		MIN	MAX	MIN	MAX	UNIT
f_{SCL}	SCL operating frequency	0.001	0.4	0.001	2.56	MHz
t_{BUF}	Bus free time between stop and start condition	1300		160		ns
$t_{HD;STA}$	Hold time after repeated start condition. After this period, the first clock is generated.	600		160		ns
$t_{SU;STA}$	Repeated start condition setup time	600		160		ns
$t_{SU;STO}$	Stop condition setup time	600		160		ns
$t_{HD;DAT}$	Data hold time when SDA	0	—[1]	0	130	ns
$t_{VD;DAT}$	Data valid time[2]	0	900	—	—	ns
$t_{SU;DAT}$	Data setup time	100		20		ns
t_{LOW}	SCL clock low period	1300		250		ns
t_{HIGH}	SCL clock high period	600		60		ns
t_F – SDA	Data fall time	20 × (V+/5.5)	300		100	ns
t_F, t_R – SCL	Clock fall and rise time		300		40	ns
t_R	Rise time for SCL ≤ 100 kHz		1000			ns
	Serial bus timeout	15	20	15	20	ms

(1) The maximum t_{HDDAT} could be 0.9 µs for Fast-Mode, and is less than the maximum t_{VDDAT} by a transition time.
(2) t_{VDDATA} = time for data signal from SCL LOW to SDA output (HIGH to LOW, depending on which is worse).

8 Detailed Description

8.1 Overview

The TMP468 is a digital temperature sensor that combines local temperature measurement channel and eight remote-junction temperature measurement channels in a single DSBGA-16 package. The device has a two-wire-interface that is compatible with I^{2}C or SMBus interfaces and includes four pin-programmable bus address options. The TMP468 is specified over a local device temperature range of –40°C to 125°C. The TMP468 also contains multiple registers for programming and holding configuration settings, temperature limits, and temperature measurement results. The TMP468 pin out includes THERM and THERM2 outputs that signal overtemperature events based on the settings of temperature limit registers.

8.2 Functional Block Diagram

Copyright © 2016, Texas Instruments Incorporated
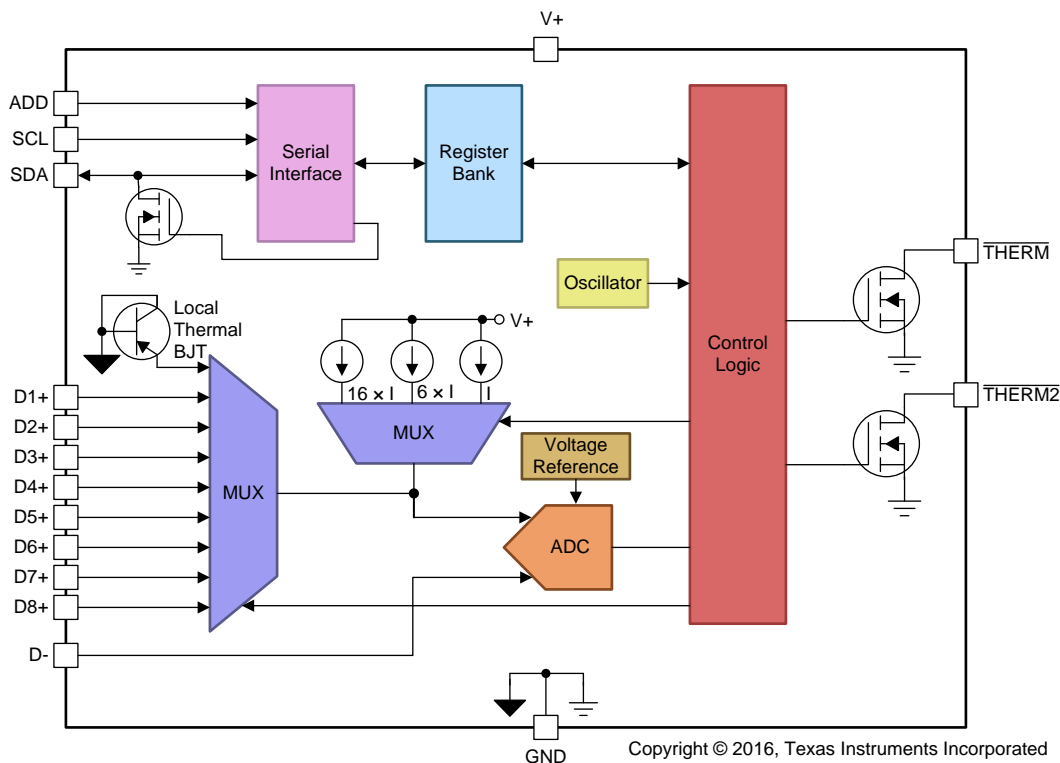

8.3 Feature Description

8.3.1 Temperature Measurement Data

The local and remote temperature sensors have a resolution of 13 bits (0.0625°C). Temperature data that result from conversions within the default measurement range are represented in binary form, as shown in the *Standard Binary* column of Table 1. Negative numbers are represented in two's complement format. The resolution of the temperature registers extends to +255.9375°C and down to –256°C but the actual device is limited to ranges as specified in the *Electrical Characteristics* to meet the accuracy specifications. The TMP468 is specified for ambient temperatures ranging from –40°C to 125°C; parameters in the *Absolute Maximum Ratings* table must be observed to prevent damage to the device.

Feature Description (continued)

127	0011 1111 1000 0000	3F 80
150	0100 1011 0000 0000	4B 00
175	0101 0111 1000 0000	57 80
191	0101 1111 1000 0000	5F 80

(1) Resolution is 0.0625°C per count. Negative numbers are represented in two's complement format.

Both local and remote temperature data use two bytes for data storage with a two's complement format for negative numbers. The high byte stores the temperature with 2°C resolution. The second or low byte stores the decimal fraction value of the temperature and allows a higher measurement resolution, as shown in Table 1. The measurement resolution for both the local and the remote channels is 0.0625°C.

8.3.2 Series Resistance Cancellation

Series resistance cancellation automatically eliminates the temperature error caused by the resistance of the routing to the remote transistor or by the resistors of the optional external low-pass filter. A total up to 1-kΩ series resistance can be cancelled by the TMP468 device, thus eliminating the need for additional characterization and temperature offset correction. See Figure 9 (*Remote Temperature Error vs Series Resistance*) for details on the effects of series resistance on sensed remote temperature error.

8.3.3 Differential Input Capacitance

The TMP468 device tolerates differential input capacitance of up to 1000 pF with minimal change in temperature error. The effect of capacitance on the sensed remote temperature error is illustrated in Figure 10 (*Remote Temperature Error vs Differential Capacitance*).

8.3.4 Sensor Fault

The TMP468 device can sense a fault at the D+ resulting from an incorrect diode connection. The TMP468 device can also sense an open circuit. Short-circuit conditions return a value of –256°C. The detection circuitry consists of a voltage comparator that trips when the voltage at D+ exceeds (V+) – 0.3 V (typical). The comparator output is continuously checked during a conversion. If a fault is detected, then the RxOP bit in the Remote Channel Status register is set to 1.

When not using the remote sensor with the TMP468 device, the corresponding D+ and D– inputs must be connected together to prevent meaningless fault warnings.

8.3.5 $\overline{\text{THERM}}$ Functions

Operation of the $\overline{\text{THERM}}$ (pin B3) and $\overline{\text{THERM2}}$ (pin C3) interrupts is shown in Figure 15.

The hysteresis value is stored in the $\overline{\text{THERM}}$ Hysteresis register and applies to both the $\overline{\text{THERM}}$ and $\overline{\text{THERM2}}$ interrupts.
Figure 15. $\overline{\text{THERM}}$ and $\overline{\text{THERM2}}$ Interrupt Operation

8.4 Device Functional Modes

8.4.1 Shutdown Mode (SD)

The TMP468 shutdown mode enables the user to save maximum power by shutting down all device circuitry other than the serial interface, and reducing current consumption to typically less than 0.3 μA; see Figure 14 (*Shutdown Quiescent Current vs Supply Voltage*). Shutdown mode is enabled when the SD bit (bit 5) of the configuration register is high; the device shuts down after the current conversion is finished. When the SD bit is low, the device maintains a continuous-conversion state.

Product Folder Links: *TMP468*

8.5 Programming

8.5.1 Serial Interface

The TMP468 operate only as a slave device on the two-wire bus (I^{2}C/SMBus). Connections to either bus are made using the open-drain I/O lines, SDA and SCL. The SDA and SCL pins feature integrated spike suppression filters and Schmitt triggers to minimize the effects of input spikes and bus noise. The TMP468 supports the transmission protocol for fast (1 kHz to 400 kHz) and high-speed (1 kHz to 2.56 MHz) modes. All data bytes are transmitted MSB first.

While the TMP468 is unpowered bus traffic on SDA and SCL may continue without any adverse effects to the communication or to the TMP468. As the TMP468 is powering up, it will not load the bus, thus bus traffic may continue undisturbed.

8.5.1.1 Bus Overview

The TMP468 device is compatible with the I^{2}C or SMBus interface. In I^{2}C or SMBus protocol, the device that initiates the transfer is called a *master*, and the devices controlled by the master are *slaves*. The bus must be controlled by a master device that generates the serial clock (SCL), controls the bus access, and generates the start and stop conditions.

To address a specific device, a start condition is initiated. A start condition is indicated by pulling the data line (SDA) from a high-to-low logic level when SCL is high. All slaves on the bus shift in the slave address byte, with the last bit indicating whether a read or write operation is intended. During the ninth clock pulse, the slave being addressed responds to the master by generating an *acknowledge* (Ack) bit and pulling SDA low.

Data transfer is then initiated and sent over eight clock pulses followed by an acknowledge bit (Ack). During data transfer, SDA must remain stable when SCL is high. A change in SDA when SCL is high is interpreted as a control signal. The TMP468 has a word register structure (16-bits wide) thus data writes must always include 2 bytes. Data transfer occurs during the Ack at the end of the second byte.

After all data are transferred, the master generates a stop condition. A stop condition is indicated by pulling SDA from low to high when SCL is high.

8.5.1.2 Bus Definitions

The TMP468 device is two-wire- and I^{2}C- or SMBus-compatible. Figure 17 through Figure 20 illustrate the timing for various operations on the TMP468. The bus definitions are as follows:

Bus Idle: Both SDA and SCL lines remain high.

Start Data Transfer: A change in the state of the SDA line (from high to low) when the SCL line is high defines a start condition. Each data transfer initiates with a start condition.

Stop Data Transfer: A change in the state of the SDA line (from low to high) when the SCL line is high defines a stop condition. Each data transfer terminates with a repeated start or stop condition.

Data Transfer: The number of data bytes transferred between a start and stop condition is not limited and is determined by the master device. The receiver acknowledges the data transfer.

Acknowledge: Each receiving device, when addressed, is obliged to generate an acknowledge bit. A device that acknowledges must pull down the SDA line during the acknowledge clock pulse in such a way that the SDA line is stable low during the high period of the acknowledge clock pulse. Take setup and hold times into account. On a master receive, data transfer termination can be signaled by the master generating a not-acknowledge on the last byte that is transmitted by the slave.

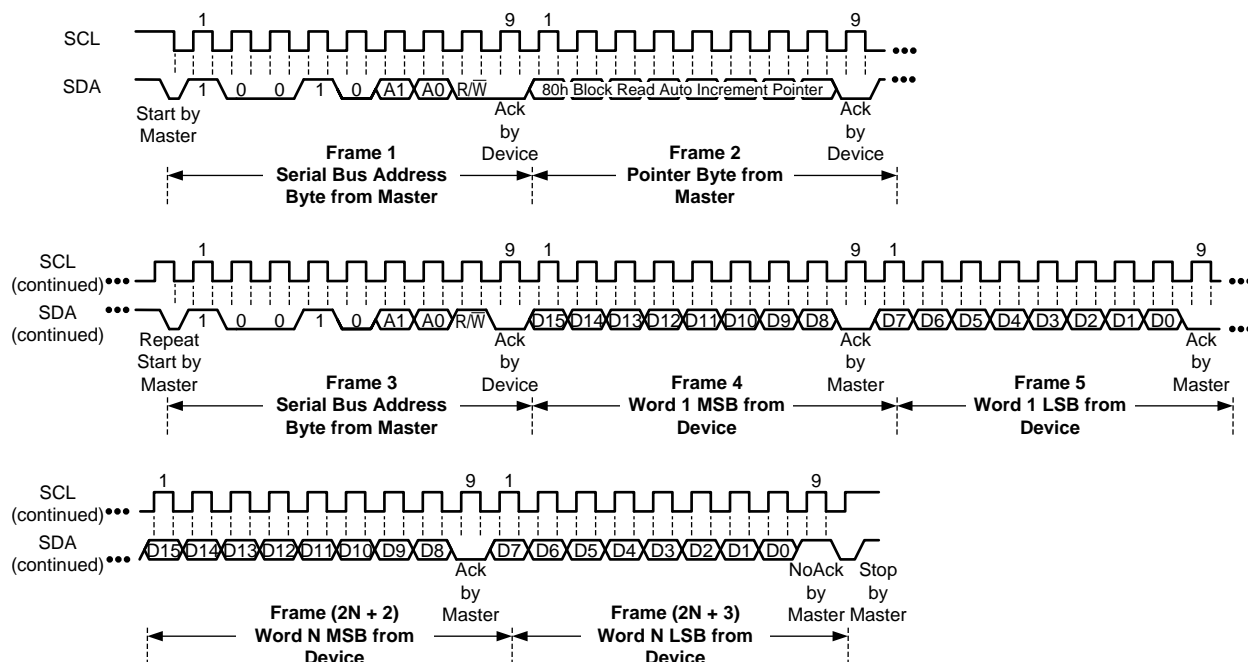

Figure 20. Two-Wire Timing Diagram for Pointer Byte Set Followed by a Repeat Start and Multiple-Word (N-Word) Read
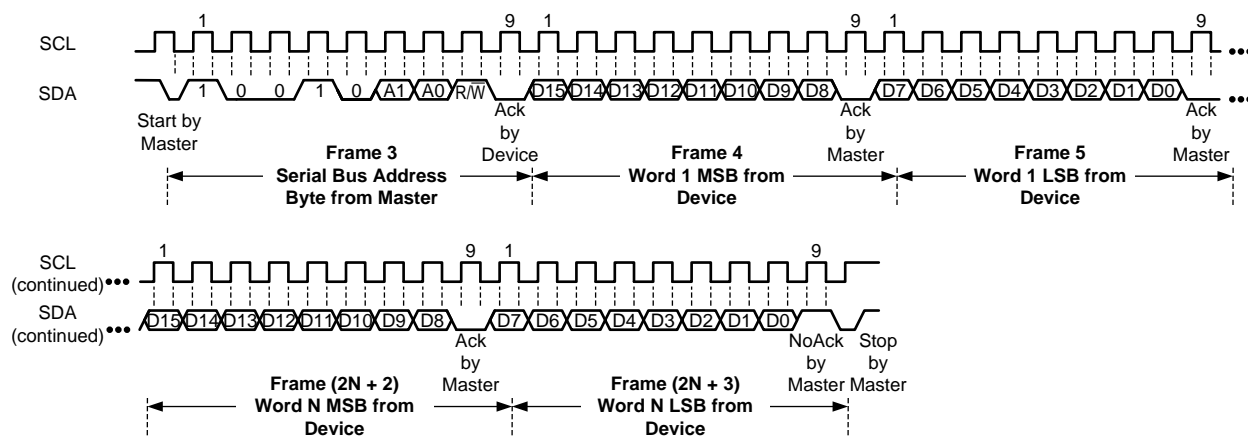

Figure 21. Two-Wire Timing Diagram for Multiple-Word (N-Word) Read Without a Pointer Byte Set

Programming (continued)

8.5.1.3 Serial Bus Address

To communicate with the TMP468, the master must first address slave devices using a slave address byte. The slave address byte consists of seven address bits and a direction bit indicating the intent of executing a read or write operation. The TMP468 allows up to four devices to be addressed on a single bus. The assigned device address depends on the ADD pin connection as described in Table 2.

Table 2. Slave Address Options

ADD PIN CONNECTION	SLAVE ADDRESS	
	BINARY	HEX
GND	1001000	48
V+	1001001	49
SDA	1001010	4A
SCL	1001011	4B

8.5.1.4 Read and Write Operations

Accessing a particular register on the TMP468 is accomplished by writing the appropriate value to the pointer register. The value for the pointer register is the first byte transferred after the slave address byte with the R/$\overline{W}$ bit low. Every write operation to the TMP468 requires a value for the pointer register (see Figure 17).

The TMP468 registers can be accessed with block or single register reads. Block reads are only supported for pointer values 80h to 88h. Registers at 80h through 88h mirror the Remote and Local temperature value registers (00h to 08h). Pointer values 00h to 08h are for single register reads.

Single Register Reads

When reading from the TMP468, the last value stored in the pointer register by a write operation is used to determine which register is read by a read operation. To change which register is read for a read operation, a new value must be written to the pointer register. This transaction is accomplished by issuing a slave address byte with the R/$\overline{W}$ bit low, followed by the pointer register byte; no additional data are required. The master can then generate a start condition and send the slave address byte with the R/$\overline{W}$ bit high to initiate the read command; see Figure 18 through Figure 20 for details of this sequence.

If repeated reads from the same register are desired, continually sending the pointer register bytes is not necessary because the TMP468 retains the pointer register value until it is changed by the next write operation. The register bytes are sent MSB first, followed by the LSB. If only one byte is read (MSB), a consecutive read of TMP468 will result in the MSB being transmitted first. The LSB can only be accessed through two-byte reads.

The master terminates a read operation by issuing a *not-acknowledge* command at the end of the last byte to be read or transmitting a Stop. For a single-byte operation, the master must leave the SDA line high during the acknowledge time of the first byte that is read from the slave.

The TMP468 register structure has a word (two-byte) length, thus every write transaction must have an even number of bytes (MSB and LSB) following the pointer register value (see Figure 17). Data transfers occur during the Ack at the end of the second byte or LSB. If the transaction does not finish, signaled by the ACK at the end of the second byte, then the data is ignored and not loaded into the TMP468 register. Read transactions do not have the same restriction and may be terminated at the end of the last MSB.

Block Register Reads

The TMP468 supports block mode reads at address 80h through 88h for temperature results alone. Setting the pointer register to 80h signals to the TMP468 that a block of more than two bytes should be transmitted before a stop is issued. In this mode the TMP468 auto increments the internal pointer. After the 18-bytes of temperature data are transmitted the internal pointer resets to 80h. If the transmission is terminated before register 88h is read, the pointer increments so a consecutive read without a pointer set can access the next register.

8.5.1.5 Timeout Function

The TMP468device resets the serial interface if either SCL or SDA are held low for 17.5 ms (typical) between a start and stop condition. If the TMP468 device is holding the bus low, the device releases the bus and waits for a start condition. To avoid activating the timeout function, maintaining a communication speed of at least 1 kHz for the SCL operating frequency is necessary.

8.5.1.6 High-Speed Mode

For the two-wire bus to operate at frequencies above 1 MHz, the master device must issue a high-speed mode (HS-mode) master code (0000 1xxx) as the first byte after a start condition to switch the bus to high-speed operation. The TMP468 does not acknowledge this byte, but switches the input filters on SDA and SCL and the output filter on SDA to operate in HS-mode, thus allowing transfers at up to 2.56 MHz. After the HS-mode master code is issued, the master transmits a two-wire slave address to initiate a data transfer operation. The bus continues to operate in HS-mode until a stop condition occurs on the bus. Upon receiving the stop condition, the TMP468 switches the input and output filters back to fast mode operation.

8.5.2 Register Reset

The TMP468 registers can be software reset by setting bit 15 of the Software Reset Register (20h) to 1. This software reset restores the power-on-reset state to all TMP468 registers and aborts any conversion in progress.

8.5.3 Lock Register

All of the configuration and limit registers may be locked for writes (making them write-protected), thus lessening the chance of software runway from issuing false changes to these registers. *Lock* column identifies which registers will be locked. Lock mode does not effect read operations. To activate the lock mode, the lock register C4h must be set to 0x5CA6. The lock only remains active while the TMP468 is powered up. Because the TMP468 does not contain non-volatile memory, the setting of the configuration and limit registers will be lost once a power cycle occurs if they are locked or unlocked.

In lock mode the TMP468 ignores a write operation to configuration and limit registers except for the Lock register C4h. The TMP468 will NOACK the data bytes during a write operation to a locked register. To unlock the TMP468 registers write 0xEB19 to register C4h. The TMP468 powers up in the locked mode, thus the registers must be unlocked before they will accept writes of new data.

8.6.1 Register Information

The TMP468 contains multiple registers for holding configuration information, temperature measurement results, and status information. These registers are described in Figure 22 and Table 3.

8.6.1.1 Pointer Register

Figure 22 shows the internal register structure of the TMP468. The 8-bit pointer register is used to address a given data register. The pointer register identifies which of the data registers must respond to a read or write command on the two-wire bus. This register is set with every write command. A write command must be issued to set the proper value in the pointer register before executing a read command. describes the pointer register and the internal structure of the TMP468 registers. The power-on-reset (POR) value of the pointer register is 00h (0000 0000b). lists a summary of the pointer values for the different registers. Writing to data to unassigned pointer values will be ignored and will not affect the operation of the device. Reading an unassigned register will return undefined data and will be ACK'd.
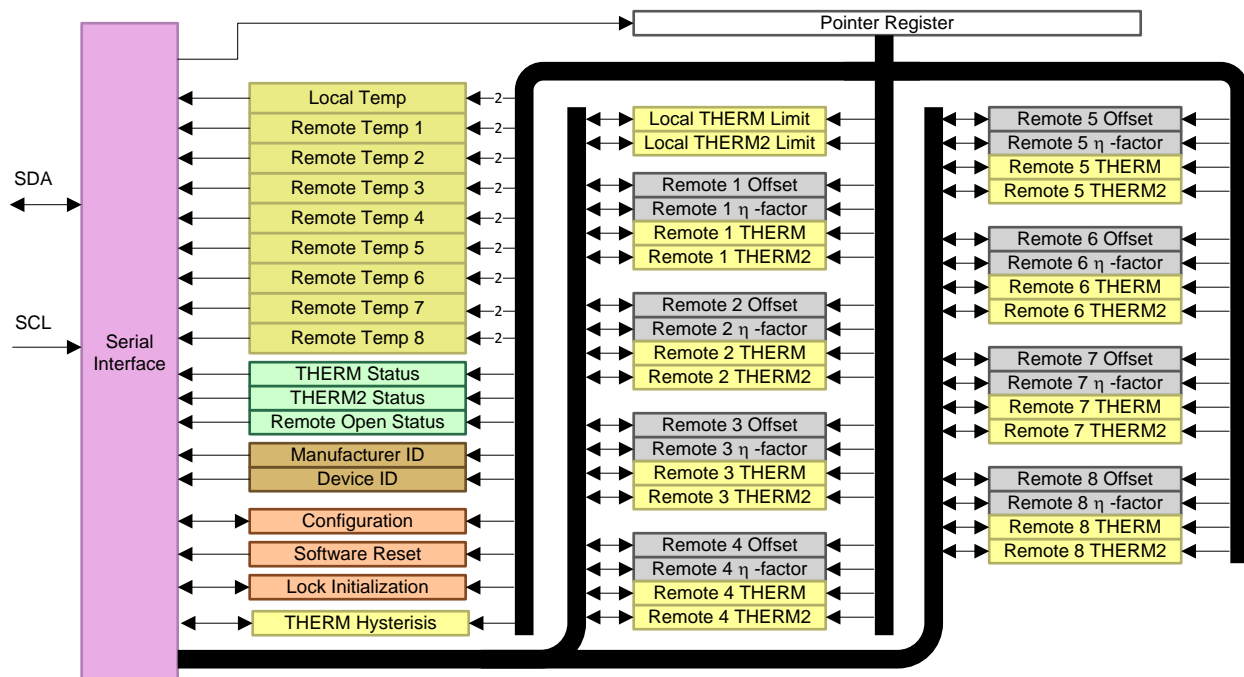

Figure 22. TMP468 Internal Register Structure

8.6.1.2 Local and Remote Temperature Value Registers

The TMP468 device has multiple 16-bit registers that hold 13-bit temperature measurement results. The 13 bits of the local temperature sensor result are stored in register 00h. The 13 bits of the eight-remote temperature-sensor results are stored in registers 01h through 08h. The four assigned LSBs of both the local (LT3:LT0) and remote (RT3:RT0) sensors indicate the temperature value after the decimal point (for example, if the temperature result is 10.0625°C, then the high byte is 0000 0101 and the low byte is 0000 1000). These registers are read-only and are updated by the ADC each time a temperature measurement is completed. Asynchronous reads are supported, thus a read operation can occur at any time and will result in valid conversion results being transmitted once the first conversion has completed after power up for the channel being accessed. If after power up a read is initiated before a conversion has completed, the read operation will result in all zeros (0x0000).

8.6.1.3 Software Reset Register

The Software Reset Register allows the user to reset the TMP458 registers through software by setting the RST (bit 15) to a 1. The power-on-reset value for this register is 0x0000. When the device is in lock mode a reset is ignored, thus writing a 1 to the RST bit will not reset any registers.

Table 4. Software Reset Register Format

STATUS REGISTER (READ = 20h, WRITE = 20h, POR = 0x0000)		
BIT NUMBER	BIT NAME	FUNCTION
15	RST	1 software reset device; writing a value of 0 will be ignored
14-0	0	Reserved for future use; will always report 0

8.6.1.4 THERM Status Register

The THERM status register reports the state of the THERM limit comparators for local and eight remote temperatures. Table 5 lists the status register bits. The THERM status register is read-only and is read by accessing pointer address 21h.

Table 5. THERM Status Register Format

THERM STATUS REGISTER (READ = 21h, WRITE = N/A)		
BIT NUMBER	BIT NAME	FUNCTION
15	R8TH	1 when remote 8 exceeds its THERM limit
14	R7TH	1 when remote 7 exceeds its THERM limit
13	R6TH	1 when remote 6 exceeds its THERM limit
12	R5TH	1 when remote 5 exceeds its THERM limit
11	R4TH	1 when remote 4 exceeds its THERM limit
10	R3TH	1 when remote 3 exceeds its THERM limit
9	R2TH	1 when remote 2 exceeds its THERM limit
8	R1TH	1 when remote 1 exceeds its THERM limit
7	LTH	1 when local sensor exceeds its THERM limit
6:0	0	Reserved for future use; will always report 0

The R8TH:R8TH and LTH flags are set when the corresponding temperature exceeds their respective programmed THERM limit (39h, 42h, 4Ah, 52h, 5Ah, 62h, 6Ah, 72h, 7Ah). These flags are reset automatically when the temperature returns below the THERM limit minus the value set in the THERM Hysteresis register (38h). The THERM output goes low in the case of overtemperature on either the local or remote channels, and goes high as soon as the measurements are less than the THERM limit minus the value set in the THERM Hysteresis register. The THERM hysteresis register (38h) allows hysteresis to be added so that the flag resets and the output goes high when the temperature returns to or goes below the limit value minus the hysteresis value.

8.6.1.5 THERM2 Status Register

The THERM2 status register reports the state of the THERM2 limit comparators for local and remote 1-8 temperatures. Table 6 lists the status register bits. The THERM2 status register is read-only and is read by accessing pointer address 22h.

Table 6. THERM2 Status Register Format

BIT NUMBER	BIT NAME	FUNCTION
THERM2 STATUS REGISTER (READ = 22h, WRITE = N/A)		
15	R8TH2	1 when remote 8 exceeds its THERM2 limit
14	R7TH2	1 when remote 7 exceeds its THERM2 limit
13	R6TH2	1 when remote 6 exceeds its THERM2 limit
12	R5TH2	1 when remote 5 exceeds its THERM2 limit
11	R4TH2	1 when remote 4 exceeds its THERM2 limit
10	R3TH2	1 when remote 3 exceeds its THERM2 limit
9	R2TH2	1 when remote 2 exceeds its THERM2 limit
8	R1TH2	1 when remote 1 exceeds its THERM2 limit
7	LTH2	1 when local sensor exceeds its THERM2 limit
6:0	0	Reserved for future use; will always report 0

The R8TH2:R1TH2 and LTH2 flags are set when the corresponding temperature exceeds their respective programmed THERM2 limit (3Ah, 43h, 4Bh, 53h, 5Bh, 63h, 6Bh, 73h, 7Bh). These flags are reset automatically when the temperature returns below the THERM2 limit minus the value set in the THERM Hysteresis register (38h). The THERM2 output goes low in the case of overtemperature on either the local or remote channels, and goes high as soon as the measurements are less than the THERM2 limit minus the value set in the THERM Hysteresis register. The THERM hysteresis register (38h) allows hysteresis to be added so that the flag resets and the output goes high when the temperature returns to or goes below the limit value minus the hysteresis value.

8.6.1.6 Remote Channel Open Status Register

The Remote Channel Open status register reports the state of the connection of remote channels one through eight. Table 7 lists the status register bits. The Remote Channel Open status register is read-only and is read by accessing pointer address 23h.

Table 7. Remote Channel Open Status Register Format

BIT NUMBER	BIT NAME	FUNCTION
REMOTE CHANNEL OPEN STATUS REGISTER (READ = 23h, WRITE = N/A)		
15	R8OPEN	1 when remote 8 channel is an open circuit
14	R7OPEN	1 when remote 7 channel is an open circuit
13	R6OPEN	1 when remote 6 channel is an open circuit
12	R5OPEN	1 when remote 5 channel is an open circuit
11	R4OPEN	1 when remote 4 channel is an open circuit
10	R3OPEN	1 when remote 3 channel is an open circuit
9	R2OPEN	1 when remote 2 channel is an open circuit
8	R1OPEN	1 when remote 1channel is an open circuit
7:0	0	Reserved for future use; will always report 0

The R8OPEN:R1OPEN bits indicate an open-circuit condition on remote sensors eight through one, respectively. The setting of these flags do not directly affect the state of the THERM or THERM2 output pins. Indirectly though the temperature reading(s) may be erroneous and thus exceed the respective THERM and THERM2 limits thus activating the THERM or THERM2 output pins.

8.6.1.7 Configuration Register

The Configuration Register sets the conversion rate, starts OneShot conversion of all enabled channels, enables conversion the temperature channels, controls the shutdown mode and reports when a conversion is in process. The configuration register is set by writing to pointer address 30h, and is read by reading from pointer address 30h. Table 8 summarizes the bits of the configuration register.

Table 8. Configuration Register Bit Descriptions

CONFIGURATION REGISTER (READ = 30h, WRITE = 30h, POR = 0xFF9C)			
BIT NUMBER	**NAME**	**FUNCTION**	**POWER-ON-RESET VALUE**
15:8	REN8:REN1	1 = enable respective remote channel 8 through 1 conversions	1111 1111
7	LEN	1 = enable local channel conversion	1
6	OS	1 = start OneShot conversion on enabled channels	0
5	SD	1 = enables device shutdown	0
4:2	CR2:CR0	Conversion Rate control bits; control conversion rates for all enabled channels from 16 seconds to continuous conversion	111
1	BUSY	1 when the ADC is converting (read only bit will ignore writes)	0
0	Reserved	—	0

The Remote Enable eight through one (REN8:REN1, bits 15:8) bits enable conversions on the respective remote channels. The Local Enable (LEN, bit 7) bit enables conversions of the local temperature channel. If all LEN and REN are set to 1 (default), this enables the ADC to convert the local and all remote temperatures. If any LEN is set to 0, the local temperature conversion is skipped and similarly if a REN is set to 0, that remote temperature conversion channel is skipped. The TMP468 steps through each enabled channel in round robin fashion in the following order LOC, REM1, REM2, ..., REM8, LOC, REM1, ... All local and remote temperatures are converted by the internal ADC by default after power up. The configuration register LEN and REN bits can be configured to achieve power savings by reducing the total ADC conversion time for applications that do not require all of the eight remote and local temperature information. Note writing all zeros to REN8-REN1 and LEN will have the same effect as SD=1 and OS=0.

The shutdown bit (SD, bit 5) enables or disables the temperature-measurement circuitry. If SD = 0 (default), the TMP468 device converts continuously at the rate set in the conversion rate register. When SD is set to 1, the TMP468 device immediately stops the conversion in progress and instantly enters a shutdown mode. When SD is set to 0 again, the TMP468 resumes continuous conversions starting with the local temperature.

The BUSY bit = 1 if the ADC is making a conversion. This bit is set to 0 if the ADC is not converting

After the TMP468 has been placed in shutdown mode, writing a 1 to the OneShot (OS, bit 6) bit starts a single ADC conversion of all the enabled temperature channels. This write operation starts one conversion and comparison cycle on either the eight local and one remote sensors or any combination of sensors, depending on the LEN and REN values as configured in the configuration register (read address 30h). The TMP468 returns to shutdown mode when the cycle completes. Table 9 details the interaction of the SD, OS, LEN and REN bits.

Table 9. Conversion Modes

WRITE			READ			FUNCTION
REN[8:1], LEN	**OS**	**SD**	**REN[8:1], LEN**	**OS**	**SD**	
All 0	—	—	all 0	0	1	Shutdown
At least 1 enabled	—	0	written value	0	0	Continuous conversion
At least 1 enabled	0	1	written value	0	1	Shutdown
At least 1 enabled	1	1	written value	1	1	One-shot conversion

The rate at which conversion occur is controlled by the Conversion Rate bits (CR2:CR0, bits 4:2). The value of CR2:CR0 bits controls the idle time between conversions but not the conversion time itself, thereby allowing the TMP468 power dissipation to be balanced with the temperature register update rate. Table 10 table describes the mapping for CR2:CR0 to the conversion rate or temperature register update rate.

Table 10. Conversion Rate

CR2:CR0	DECIMAL VALUE	FREQUENCY (Hz)	TIME (s)
000	0	0.0625	16
001	1	0.125	8
010	2	0.25	4
011	3	0.5	2
100	4	1	1
101	5	2	0.5
110	6	4	0.25
111	7	Continuous Conversion; Depends on number of enabled channels; see Table 11 (default)	

Table 11. Continuous Conversion Times

		CONVERSION TIME (ms)	
		LOCAL ENABLED	LOCAL DISABLED
Number of Remote Channels Enabled	0	0.0	15.5
	1	15.8	31.3
	2	31.6	47.1
	3	47.4	62.9
	4	63.2	78.7
	5	79.0	94.5
	6	94.8	110.3
	7	110.6	126.1
	8	126.4	141.9

The remaining bits of the configuration register are reserved and must always be set to 0. The power-on-reset value for this register is 0xFF9C.

8.6.1.8 η-Factor Correction Register

The TMP468 device allows for a different η-factor value to be used for converting remote channel measurements to temperature for each temperature channel. There are 8 η-Factor Correction Registers assigned, one to each of the remote input channels (addresses 41h, 49h, 51h, 59h, 61h, 69h, 71h and 79h). Each remote channel uses sequential current excitation to extract a differential V_{BE} voltage measurement to determine the temperature of the remote transistor. Equation 1 shows this voltage and temperature.

$$V_{BE2} - V_{BE1} = \frac{\eta kT}{q} \ln\left(\frac{I_2}{I_1}\right)$$

(1)

The value η in Equation 1 is a characteristic of the particular transistor used for the remote channel. The power-on-reset value for the TMP468 device is η = 1.008. The value in the η-factor correction register can be used to adjust the effective η-factor according to Equation 2 and Equation 3.

$$\eta_{eff} = \left(\frac{1.008 \times 2088}{2088 + N_{ADJUST}}\right)$$

(2)

$$N_{ADJUST} = \left(\frac{1.008 \times 2088}{\eta_{eff}}\right) - 2088$$

(3)

Product Folder Links: *TMP468*

The η-factor correction value must be stored in twos complement format, yielding an effective data range from –128 to 127. The register power-on-reset value for each register is 0000h, thus having no effect unless a different value is written to it. The resolution of the η-factor register changes linearly as the code changes and has a range of 0.0004292 to 0.0005476, with an average of 0.0004848.

Table 12. η-Factor Range

N$_{ADJUST}$ (BITS 15 - 8 IN REGISTER ONLY SHOWN)			η
BINARY	HEX	DECIMAL	
0111 1111	7F	127	0.950205
0000 1010	0A	10	1.003195
0000 1000	08	8	1.004153
0000 0110	06	6	1.005112
0000 0100	04	4	1.006073
0000 0010	02	2	1.007035
0000 0001	01	1	1.007517
0000 0000	00	0	1.008
1111 1111	FF	–1	1.008483
1111 1110	FE	–2	1.008966
1111 1100	FC	–4	1.009935
1111 1010	FA	–6	1.010905
1111 1000	F8	–8	1.011877
1111 0110	F6	–10	1.012851
1000 0000	80	–128	1.073829

8.6.1.9 Remote Temperature Offset Register

The offset registers allow the TMP468 device to store any system offset compensation value that may result from precision calibration. The value in these registers is added to the remote temperature results upon every conversion. Each of the 8 temperature channels have an independent assigned offset register (addresses 40h, 48h, 50h, 58h, 60h, 68h, 70h, and 78h). Combined with the independent η-factor corrections, this function allows for very accurate system calibration over the entire temperature range for each remote channel. The format of these registers is the same as the temperature value registers with a range of 127.9375 to –128. Take care to program this register with sign extension, as values above 127.9375 and below –128 are not supported.

8.6.1.10 THERM Hysteresis Register

The THERM hysteresis register (address 38h) sets the value of the hysteresis used by the temperature comparison logic. All temperature reading comparisons have a common hysteresis. Hysteresis prevents oscillations from occurring on the THERM and THERM2 outputs as the measured temperature approaches the comparator threshold (see THERM Functions). The resolution of the THERM hysteresis register is 1°C and it has a range of 0°C to 255°C.

8.6.1.11 Local and Remote THERM and THERM2 Limit Registers

Each of the 8 local and the remote temperature channels has associated independent THERM and THERM2 limit registers. There are 9 THERM registers (addresses 39h, 42h, 4Ah, 52h, 5Ah, 62h, 6Ah, 72h, and 7Ah) and 9 THERM2 registers (addresses 39h, 43h, 4Bh, 53h, 5Bh, 63h, 6Bh, 73h, and 7Bh), 18 registers in total. The resolution of these registers is 0.5°C and the range is +255.5°C to –255°C. See THERM Functions for more information.

Setting a THERM limit to 255.5 will disable the THERM limit comparison for that particular channel and will disable the limit flag from being set in the THERM Status Register. Thus, preventing the associated channel from activating the THERM output. THERM2 limits, status, and outputs function similarly.

8.6.1.12 Block Read - Auto Increment Pointer

Block reads can be initiated by setting the pointer register to 80h to 87h. The temperature results are mirrored at pointer addresses 80h to 88h. Thus, temperature results for all the channels can be read with one read transaction. Setting the pointer register to any address from 80h to 88h signals to the TMP468 that a block of more than two bytes should be transmitted before a stop is issued. In this mode the TMP468 auto increments the pointer address. After 88h the pointer resets to 80h. The master should NACK the last byte read so the TMP468 will discontinue driving the bus allowing the master to initiate a stop. In this mode the pointer continuously loops in the address range of 80h to 88h, thus the register may be easily read multiple times. Block read will not disrupt the conversion process.

8.6.1.13 Lock Registers

Register C4h allows the locking of the device configuration and limit registers as shown by the Lock column in . Simply writing 0x5CA6 to the register locks these registers. To unlock the registers, simply write 0xEB19. When the lock function is enabled, reading this register will yield 0x8000; when unlocked 0x0000 will be transmitted.

8.6.1.14 Manufacturer and Device Identification Plus Revision Registers

The TMP468 device allows for the two-wire bus controller to query the device for manufacturer and device IDs to enable software identification of the device at the particular two-wire bus address. The manufacturer ID is obtained by reading from pointer address FEh; the device ID is obtained from register FFh. Note that the most significant byte of the Device ID register will be used to identify the TMP468 revision level. The TMP468 device reads 0x5449 for the manufacturer code and 0x0468 for the device ID code for the first release.

Product Folder Links: *TMP468*

9 Application and Implementation

> **NOTE**
> Information in the following applications sections is not part of the TI component specification, and TI does not warrant its accuracy or completeness. TI's customers are responsible for determining suitability of components for their purposes. Customers should validate and test their design implementation to confirm system functionality.

9.1 Application Information

The TMP468 requires a transistor connected between the D+ and D– pins for remote temperature measurement. Tie the D+ pin to GND if the remote channel is not used and only the local temperature is measured. The SDA, ALERT, and THERM pins (and SCL, if driven by an open-drain output) require pullup resistors as part of the communication bus. A 0.1-µF power-supply decoupling capacitor is recommended for local bypassing. Figure 23 and Figure 24 illustrate the typical configurations for the TMP468.

9.2 Typical Application
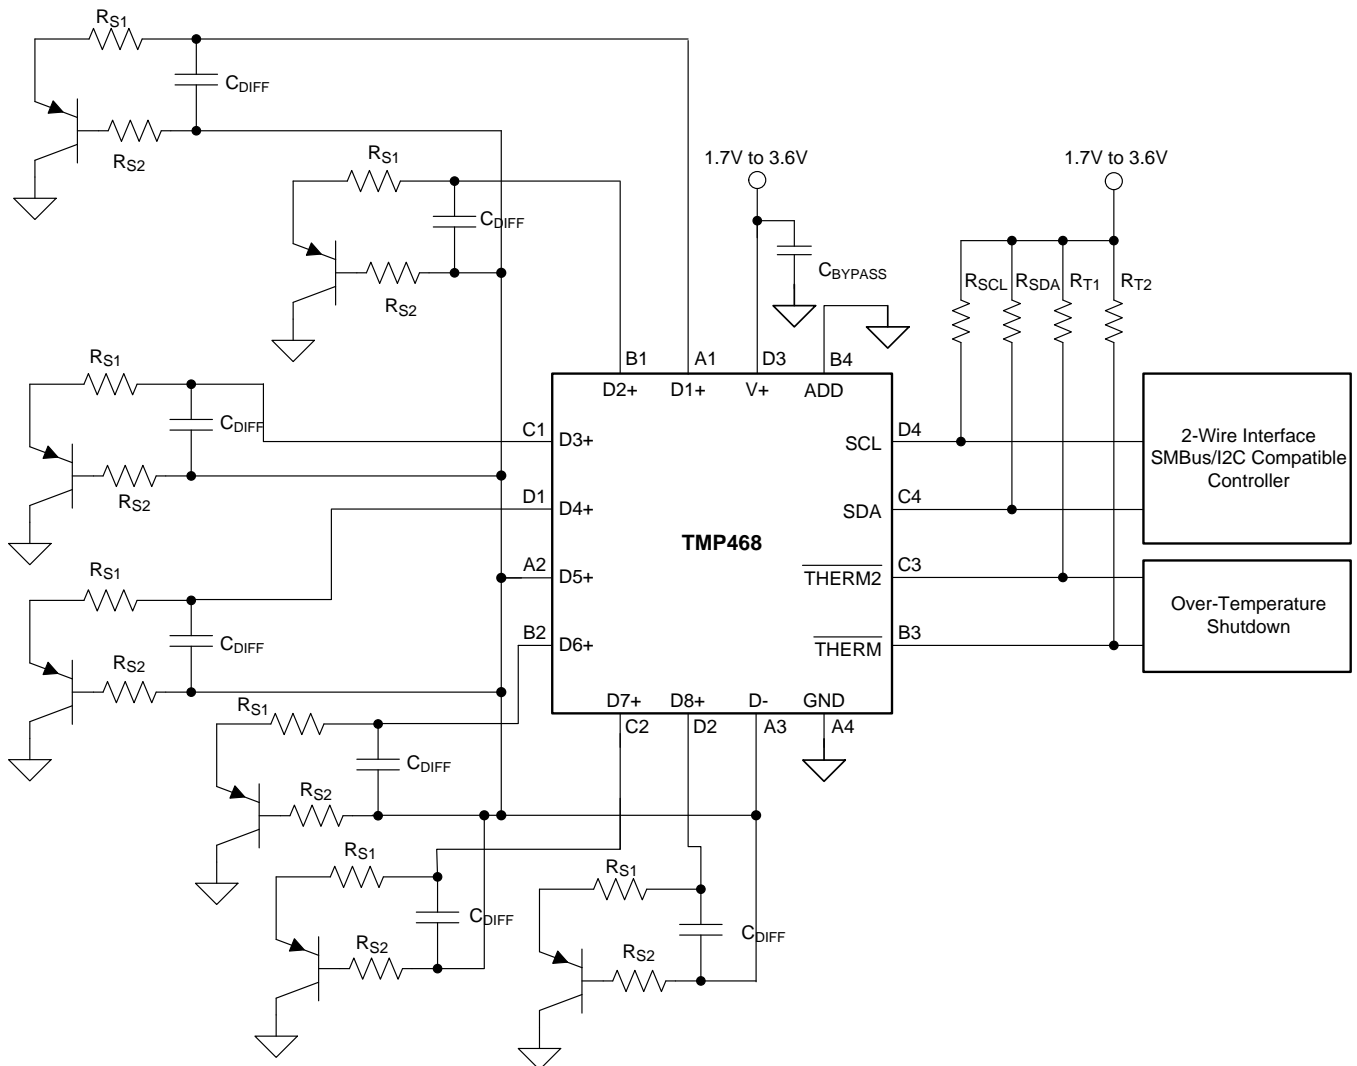

Copyright © 2016, Texas Instruments Incorporated

(1) The diode-connected configuration provides better settling time. The transistor-connected configuration provides better series resistance cancellation. Recommended diodes are MMBT3904 or MMBT3906 with n-factor setting of 1.003674 (N_{ADJUST} = 9).

(2) R_S (optional) is < 1 kΩ in most applications. R_S is the combined series resistance connected externally to the D+, D– pins. R_S selection depends on the application.

(3) C_{DIFF} (optional) is < 1000 pF in most applications. C_{DIFF} selection depends on the application; see Figure 9 (*Remote Temperature Error vs Differential Capacitance*).

(4) Unused diode channels must be tied to D– as shown for D5+.

Figure 23. TMP468 Basic Connections Using a Discrete Remote Transistor

Typical Application (continued)
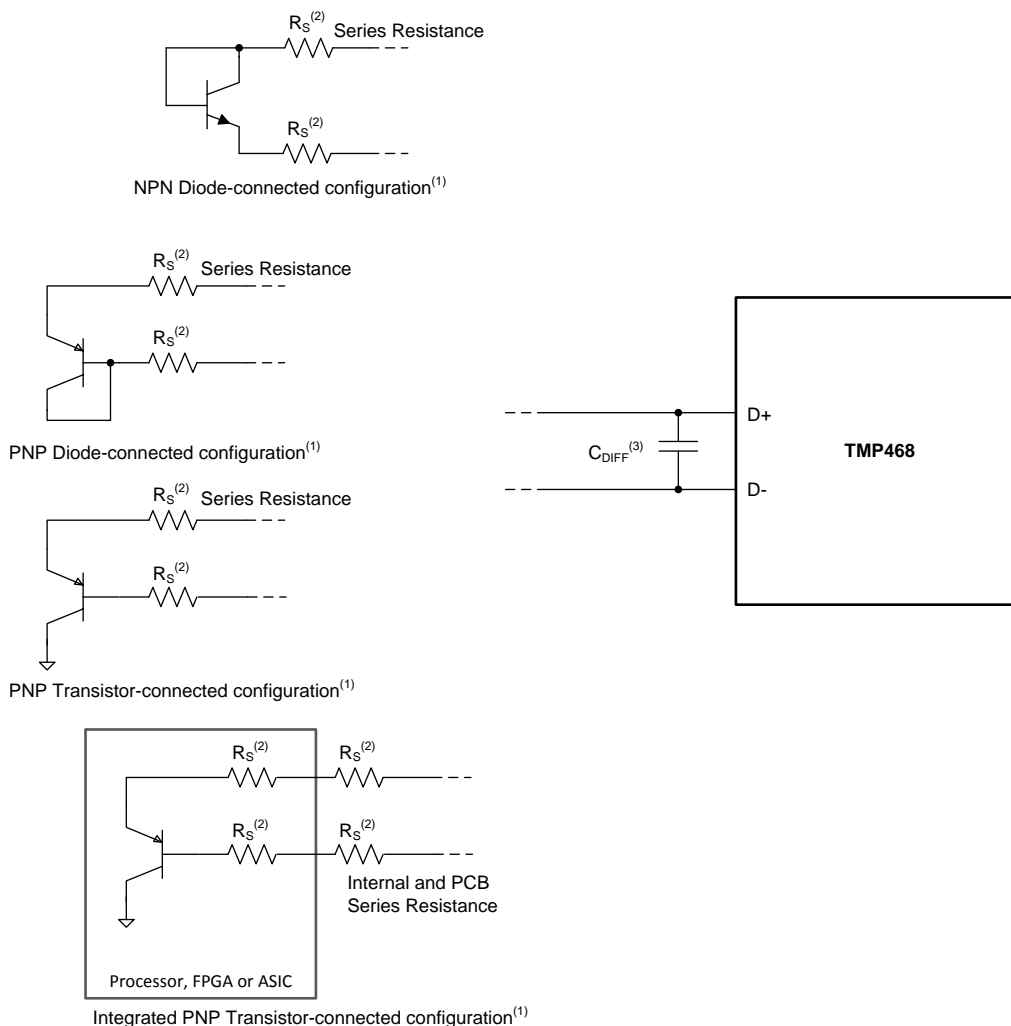

Figure 24. TMP468 Remote Transistor Options

9.2.1 Design Requirements

The TMP468 device is designed to be used with either discrete transistors or substrate transistors built into processor chips, field programmable gate arrays (FPGAs) and application-specific integrated circuits (ASICs), (see Figure 24). Either NPN or PNP transistors can be used, as long as the base-emitter junction is used as the remote temperature sense. NPN transistors must be diode-connected. PNP transistors can either be transistor- or diode-connected (see Figure 24).

Errors in remote temperature sensor readings are typically the consequence of the ideality factor (n-factor) and current excitation used by the TMP468 device versus the manufacturer-specified operating current for a given transistor. Some manufacturers specify a high-level and low-level current for the temperature-sensing substrate transistors. The TMP468 uses 7.5 μA (typical) for I_{LOW} and 120 μA (typical) for I_{HIGH}.

The ideality factor (η-factor) is a measured characteristic of a remote temperature sensor diode as compared to an ideal diode. The TMP468 allows for different η-factor values; see the *η-Factor Correction Register* section.

The n-factor for the TMP468 is trimmed to be 1.008. For transistors that have an ideality factor that does not match the TMP468, Equation 4 can be used to calculate the temperature error.

Typical Application (continued)

> **NOTE**
> For Equation 4 to be used correctly, the actual temperature (°C) must be converted to Kelvin (K).

$$T_{ERR} = \left(\frac{\eta - 1.008}{1.008}\right) \times (273.15 + T(°C))$$

where

- T_{ERR} = error in the TMP468 device because $\eta \neq 1.008$,
- η = ideality factor of the remote temperature sensor,
- $T(°C)$ = actual temperature, and

(4)

In Equation 4, the degree of delta is the same for °C and K.

For $\eta = 1.004$ and $T(°C) = 100°C$:

$$T_{ERR} = \left(\frac{1.004 - 1.008}{1.008}\right) \times (273.15 + 100°C)$$

$$T_{ERR} = -1.48°C$$

(5)

If a discrete transistor is used as the remote temperature sensor with the TMP468, the best accuracy can be achieved by selecting the transistor according to the following criteria:

1. Base-emitter voltage is > 0.25 V at 7.5 μA, at the highest-sensed temperature.
2. Base-emitter voltage is < 0.95 V at 120 μA, at the lowest-sensed temperature.
3. Base resistance is < 100 Ω.
4. Tight control of V_{BE} characteristics indicated by small variations in h_{FE} (that is, 50 to 150).

Based on this criteria, two recommended small-signal transistors are the 2N3904 (NPN) or 2N3906 (PNP).

9.2.2 Detailed Design Procedure

The local temperature sensor inside the TMP468 is influenced by the ambient air around the device but mainly monitors the PCB temperature that it is mounted to. The thermal time constant for the TMP468 device is approximately two seconds. This constant implies that if the ambient air changes quickly by 100°C, then the TMP468 device takes approximately 10 seconds (that is, five thermal time constants) to settle to within 1°C of the final value. In most applications, the TMP468 package is in electrical, and therefore thermal, contact with the printed-circuit board (PCB), as well as subjected to forced airflow. The accuracy of the measured temperature directly depends on how accurately the PCB and forced airflow temperatures represent the temperature that the TMP468 is measuring. Additionally, the internal power dissipation of the TMP468 can cause the temperature to rise above the ambient or PCB temperature. The internal power is negligible because of the small current drawn by TMP468. Equation 6 can be used to calculate the average conversion current for power dissipation and self-heating based on the number of conversions per second and temperature sensor channel enabled. Equation 7 shows an example with local and all remote sensor channels enabled and 16 conversions per second; see the *Electrical Characteristics* table for typical values required for these calculations. For a 3.3-V supply and a conversion rate of 1 conversion per second, the TMP468 device dissipates 0.224 mW (PD_{IQ} = 3.3 V × 68 μA) when both the remote and local channels are enabled.

$$\begin{aligned}
AverageConversionCurrent =\ & (LocalConversionTime) \cdot (ConversionsPerSecond) \cdot (LocalActive_Q) \\
& + (RemoteConversionTime) \cdot (ConversionsPerSecond) \cdot (RemoteActive_Q) \cdot (NumberOfActiveChannels) \\
& + (StandbyModel_Q) \cdot [1 - ((LocalConversionTime) + (RemoteConversionTime) \cdot (NumberOfActiveChannels)) \cdot (ConversionsPerSecond)]
\end{aligned}$$

(6)

Typical Application (continued)

$$
\begin{aligned}
AverageConversionCurrent &= (16ms) \cdot (\frac{1}{sec}) \cdot (240\mu A) \\
&+ (16ms) \cdot (\frac{1}{sec}) \cdot (400\mu A) \cdot (8) \\
&+ (15\mu A) \cdot \left[1 - ((16ms) + (16ms) \cdot (8)) \cdot (\frac{1}{sec}) \right] \\
&= 68\mu A
\end{aligned}
$$

(7)

The temperature measurement accuracy of the TMP468 depends on the remote and local temperature sensor being at the same temperature as the system point being monitored. If the temperature sensor is not in good thermal contact with the part of the system being monitored, then there is a delay between the sensor response and the system changing temperature. This delay is usually not a concern for remote temperature-sensing applications that use a substrate transistor (or a small, SOT-23 transistor) placed close to the device being monitored.

9.2.3 Application Curve

Figure 25 shows the typical step response to submerging a TMP468 in an oil bath with a temperature of 100°C and logging the local temperature readings.
Figure 25. Temperature Step Response of Local Sensor

10 Power Supply Recommendations

The TMP468 operates with a power-supply range of 1.7 V to 3.6 V. The device is optimized for operation at a 1.8-V supply but can measure temperature accurately in the full supply range.

TI recommends a power-supply bypass capacitor. Place this capacitor as close as possible to the supply and ground pins of the device. A typical value for this supply bypass capacitor is 0.1 μF. Applications with noisy or high-impedance power supplies may require additional decoupling capacitors to reject power-supply noise.

Product Folder Links: *TMP468*

11 Layout

11.1 Layout Guidelines

Remote temperature sensing on the TMP468 device measures very small voltages using very low currents; therefore, noise at the device inputs must be minimized. Most applications using the TMP468 have high digital content, with several clocks and a multitude of logic-level transitions that create a noisy environment. Layout must adhere to the following guidelines:

1. Place the TMP468 device as close to the remote junction sensor as possible.

2. Route the D+ and D– traces next to each other and shield them from adjacent signals through the use of ground guard traces, as shown in Figure 26. If a multilayer PCB is used, bury these traces between the ground or V+ planes to shield them from extrinsic noise sources. 5-mil (0.127 mm) PCB traces are recommended.

3. Minimize additional thermocouple junctions caused by copper-to-solder connections. If these junctions are used, make the same number and approximate locations of copper-to-solder connections in both the D+ and D– connections to cancel any thermocouple effects.

4. Use a 0.1-μF local bypass capacitor directly between the V+ and GND of the TMP468. For optimum measurement performance, minimize filter capacitance between D+ and D– to 1000 pF or less. This capacitance includes any cable capacitance between the remote temperature sensor and the TMP468.

5. If the connection between the remote temperature sensor and the TMP468 is wired and is less than 8-in (20.32 cm) long, use a twisted-wire pair connection. For lengths greater than 8 inches, use a twisted, shielded pair with the shield grounded as close to the TMP468 device as possible. Leave the remote sensor connection end of the shield wire open to avoid ground loops and 60-Hz pickup.

6. Thoroughly clean and remove all flux residue in and around the pins of the TMP468 to avoid temperature offset readings as a result of leakage paths between D+ and GND, or between D+ and V+.
NOTE: Use a minimum of 5-mil (0.127 mm) traces with 5-mil spacing.

Figure 26. Suggested PCB Layer Cross-Section

TMP468AIYFFT	ACTIVE	DSBGA	YFF	16	250	Green (RoHS & no Sb/Br)	SNAGCU	Level-1-260C-UNLIM	-40 to 125	TMP468	Samples

(1) The marketing status values are defined as follows:

ACTIVE: Product device recommended for new designs.

LIFEBUY: TI has announced that the device will be discontinued, and a lifetime-buy period is in effect.

NRND: Not recommended for new designs. Device is in production to support existing customers, but TI does not recommend using this part in a new design.

PREVIEW: Device has been announced but is not in production. Samples may or may not be available.

OBSOLETE: TI has discontinued the production of the device.

(2) Eco Plan - The planned eco-friendly classification: Pb-Free (RoHS), Pb-Free (RoHS Exempt), or Green (RoHS & no Sb/Br) - please check http://www.ti.com/productcontent for the latest availability information and additional product content details.

TBD: The Pb-Free/Green conversion plan has not been defined.

Pb-Free (RoHS): TI's terms "Lead-Free" or "Pb-Free" mean semiconductor products that are compatible with the current RoHS requirements for all 6 substances, including the requirement that lead not exceed 0.1% by weight in homogeneous materials. Where designed to be soldered at high temperatures, TI Pb-Free products are suitable for use in specified lead-free processes.

Pb-Free (RoHS Exempt): This component has a RoHS exemption for either 1) lead-based flip-chip solder bumps used between the die and package, or 2) lead-based die adhesive used between the die and leadframe. The component is otherwise considered Pb-Free (RoHS compatible) as defined above.

Green (RoHS & no Sb/Br): TI defines "Green" to mean Pb-Free (RoHS compatible), and free of Bromine (Br) and Antimony (Sb) based flame retardants (Br or Sb do not exceed 0.1% by weight in homogeneous material)

(3) MSL, Peak Temp. - The Moisture Sensitivity Level rating according to the JEDEC industry standard classifications, and peak solder temperature.

(4) There may be additional marking, which relates to the logo, the lot trace code information, or the environmental category on the device.

(5) Multiple Device Markings will be inside parentheses. Only one Device Marking contained in parentheses and separated by a "~" will appear on a device. If a line is indented then it is a continuation of the previous line and the two combined represent the entire Device Marking for that device.

(6) Lead/Ball Finish - Orderable Devices may have multiple material finish options. Finish options are separated by a vertical ruled line. Lead/Ball Finish values may wrap to two lines if the finish value exceeds the maximum column width.
