

## Very high accuracy (5 $\mu$ V) zero drift micropower 5 V operational amplifiers

Datasheet - production data

### Features

- Very high accuracy and stability: offset voltage 5  $\mu$ V max at 25 °C, 8  $\mu$ V over full temperature range (-40 °C to 125 °C)
- Rail-to-rail input and output
- Low supply voltage: 1.8 - 5.5 V
- Low power consumption: 40  $\mu$ A max. at 5 V
- Gain bandwidth product: 400 kHz
- High tolerance to ESD: 4 kV HBM
- Extended temperature range: -40 to 125 °C
- Micro-packages: SC70-5, DFN8 2x2, and QFN16 3x3

### Benefits

- Higher accuracy without calibration
- Accuracy virtually unaffected by temperature change

### Related products

- See [TSV711](#) or [TSV731](#) for continuous-time precision amplifiers

### Applications

- Battery-powered applications
- Portable devices
- Signal conditioning
- Medical instrumentation

### Description

The TSZ12x series of high precision operational amplifiers offer very low input offset voltages with virtually zero drift.

TSZ121 is the single version, TSZ122 the dual version, and TSZ124 the quad version, with pinouts compatible with industry standards.

The TSZ12x series offers rail-to-rail input and output, excellent speed/power consumption ratio, and 400 kHz gain bandwidth product, while consuming less than 40  $\mu$ A at 5 V. The devices also feature an ultra-low input bias current.

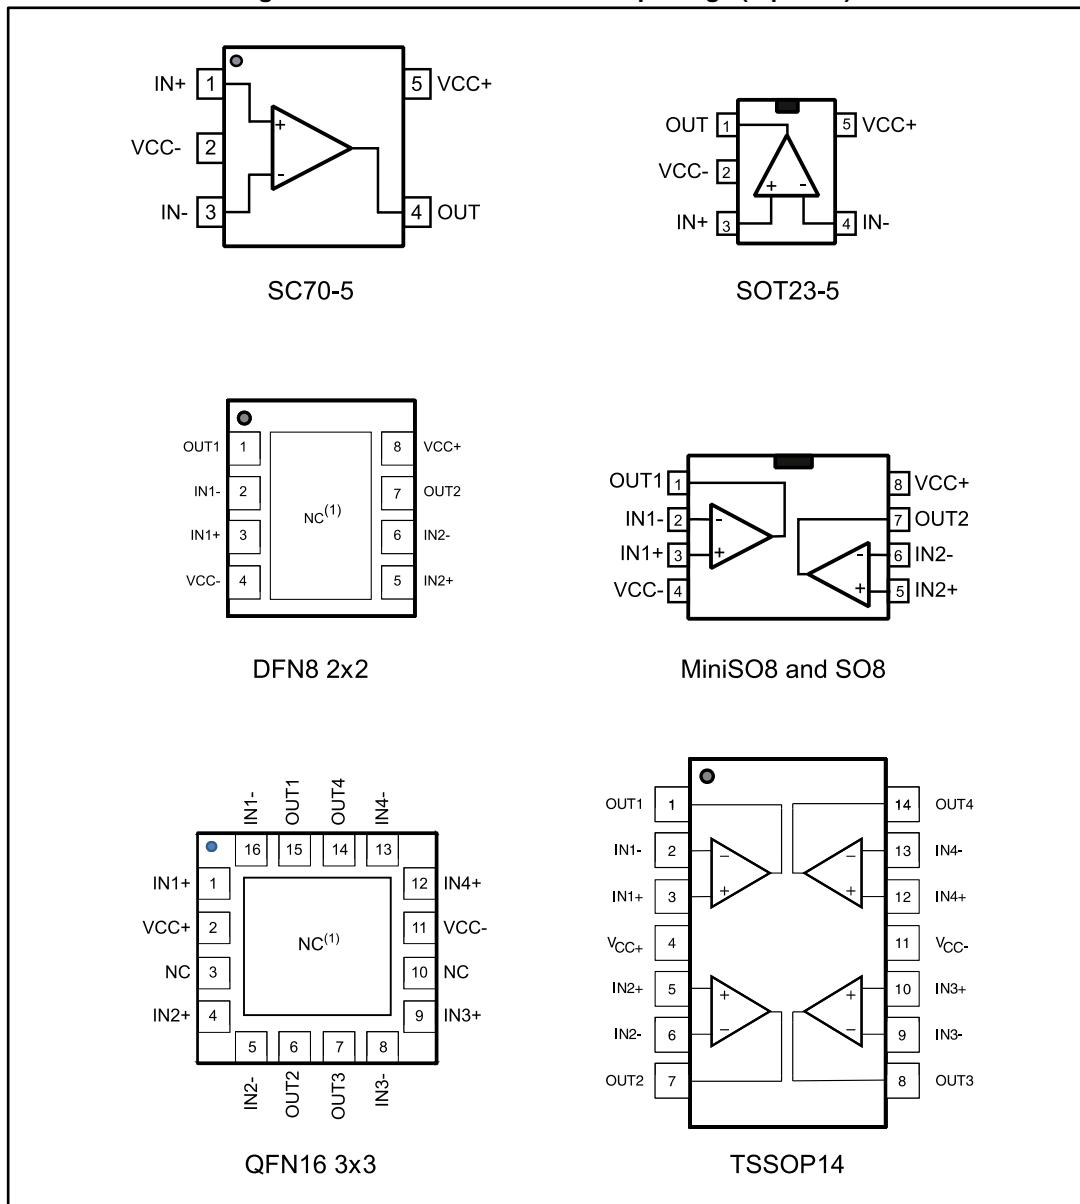

These features make the TSZ12x family ideal for sensor interfaces, battery-powered applications and portable applications.

# 1 Package pin connections

Figure 1: Pin connections for each package (top view)

1. The exposed pads of the DFN8 2x2 and the QFN16 3x3 can be connected to VCC- or left floating.

## 2 Absolute maximum ratings and operating conditions

Table 1: Absolute maximum ratings (AMR)

Symbol	Parameter	Value	Unit
V <sub>CC</sub>	Supply voltage <sup>(1)</sup>	6	V
V <sub>ID</sub>	Differential input voltage <sup>(2)</sup>	±V <sub>CC</sub>	
V <sub>IN</sub>	Input voltage <sup>(3)</sup>	(V <sub>CC-</sub> ) - 0.2 to (V <sub>CC+</sub> ) + 0.2	
I <sub>IN</sub>	Input current <sup>(4)</sup>	10	
T <sub>STG</sub>	Storage temperature	-65 to 150	
T <sub>J</sub>	Maximum junction temperature	150	°C
R <sub>THJA</sub>	Thermal resistance junction to ambient <sup>(5) (6)</sup>	SC70-5	°C/W
		SOT23-5	
		DFN8 2x2	
		MiniSO8	
		SO8	
		QFN16 3x3	
		TSSOP14	
ESD	HBM: human body model <sup>(7)</sup>	4	kV
	MM: machine model <sup>(8)</sup>	300	V
	CDM: charged device model <sup>(9)</sup>	1.5	kV
	Latch-up immunity	200	mA

**Notes:**

<sup>(1)</sup>All voltage values, except the differential voltage are with respect to the network ground terminal.

<sup>(2)</sup>The differential voltage is the non-inverting input terminal with respect to the inverting input terminal.

<sup>(3)</sup>V<sub>CC</sub> - V<sub>IN</sub> must not exceed 6 V, Vin must not exceed 6 V

<sup>(4)</sup>Input current must be limited by a resistor in series with the inputs.

<sup>(5)</sup>R<sub>th</sub> are typical values.

<sup>(6)</sup>Short-circuits can cause excessive heating and destructive dissipation.

<sup>(7)</sup>Human body model: 100 pF discharged through a 1.5 kΩ resistor between two pins of the device, done for all couples of pin combinations with other pins floating.

<sup>(8)</sup>Machine model: a 200 pF cap is charged to the specified voltage, then discharged directly between two pins of the device with no external series resistor (internal resistor < 5 Ω), done for all couples of pin combinations with other pins floating.

<sup>(9)</sup>Charged device model: all pins plus package are charged together to the specified voltage and then discharged directly to ground.

Table 2: Operating conditions

Symbol	Parameter	Value	Unit
V <sub>CC</sub>	Supply voltage	1.8 to 5.5	V
V <sub>ICM</sub>	Common mode input voltage range	(V <sub>CC-</sub> ) - 0.1 to (V <sub>CC+</sub> ) + 0.1	
T <sub>OPER</sub>	Operating free air temperature range	-40 to 125

## 5 Application information

### 5.1 Operation theory

The TSZ121, TSZ122, and TSZ124 are high precision CMOS devices. They achieve a low offset drift and no 1/f noise thanks to their chopper architecture. Chopper-stabilized amps constantly correct low-frequency errors across the inputs of the amplifier.

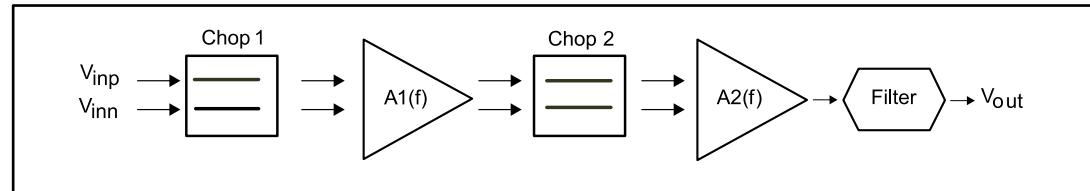

Chopper-stabilized amplifiers can be explained with respect to:

- Time domain
- Frequency domain

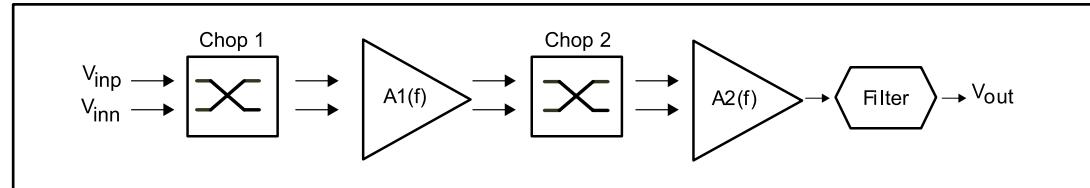

#### 5.1.1 Time domain

The basis of the chopper amplifier is realized in two steps. These steps are synchronized thanks to a clock running at 400 kHz.

**Figure 38: Block diagram in the time domain (step 1)**

**Figure 39: Block diagram in the time domain (step 2)**

*Figure 38: "Block diagram in the time domain (step 1)"* shows step 1, the first clock cycle, where  $V_{io}$  is amplified in the normal way.

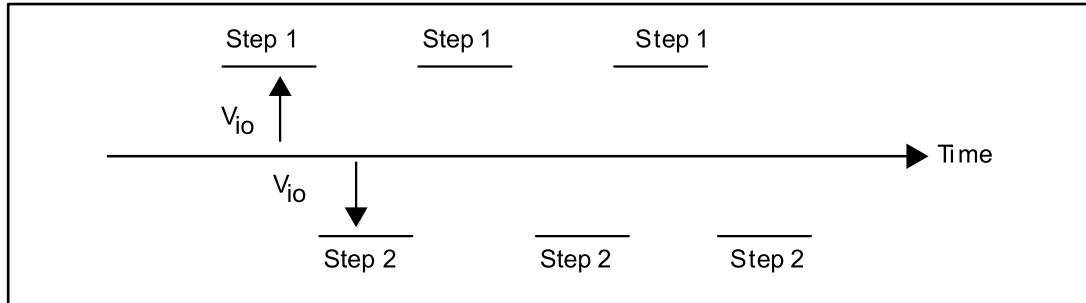

*Figure 39: "Block diagram in the time domain (step 2)"* shows step 2, the second clock cycle, where Chop1 and Chop2 swap paths. At this time, the  $V_{io}$  is amplified in a reverse way as compared to step 1.

At the end of these two steps, the average  $V_{io}$  is close to zero.

The A2(f) amplifier has a small impact on the  $V_{io}$  because the  $V_{io}$  is expressed as the input offset and is consequently divided by A1(f).

In the time domain, the offset part of the output signal before filtering is shown in *Figure 40: "V<sub>io</sub> cancellation principle"*.

Figure 40: Vio cancellation principle

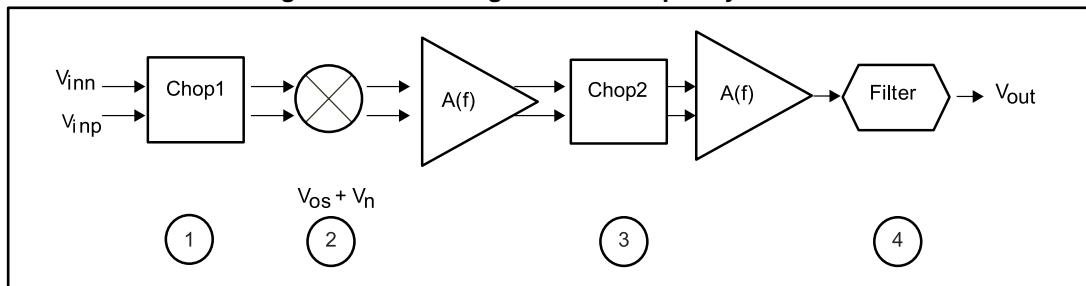

The low pass filter averages the output value resulting in the cancellation of the  $V_{io}$  offset.

The 1/f noise can be considered as an offset in low frequency and it is canceled like the  $V_{io}$ , thanks to the chopper technique.

### 5.1.2 Frequency domain

The frequency domain gives a more accurate vision of chopper-stabilized amplifier architecture.

Figure 41: Block diagram in the frequency domain

The modulation technique transposes the signal to a higher frequency where there is no 1/f noise, and demodulate it back after amplification.

1. According to [Figure 41: "Block diagram in the frequency domain"](#), the input signal  $V_{in}$  is modulated once (Chop1) so all the input signal is transposed to the high frequency domain.
2. The amplifier adds its own error ( $V_{io}$  (output offset voltage) + the noise  $V_n$  (1/f noise)) to this modulated signal.
3. This signal is then demodulated (Chop2), but since the noise and the offset are modulated only once, they are transposed to the high frequency, leaving the output signal of the amplifier without any offset and low frequency noise. Consequently, the input signal is amplified with a very low offset and 1/f noise.
4. To get rid of the high frequency part of the output signal (which is useless) a low pass filter is implemented.

To further suppress the remaining ripple down to a desired level, another low pass filter may be added externally on the output of the TSZ121, TSZ122, or TSZ124 device.

## 5.2 Operating voltages

TSZ121, TSZ122, and TSZ124 devices can operate from 1.8 to 5.5 V. The parameters are fully specified for 1.8 V, 3.3 V, and 5 V power supplies. However, the parameters are very stable in the full  $V_{CC}$  range and several characterization curves show the TSZ121, TSZ122, and TSZ124 device characteristics at 1.8 V and 5.5 V. Additionally, the main specifications are guaranteed in extended temperature ranges from -40 to 125 °C.

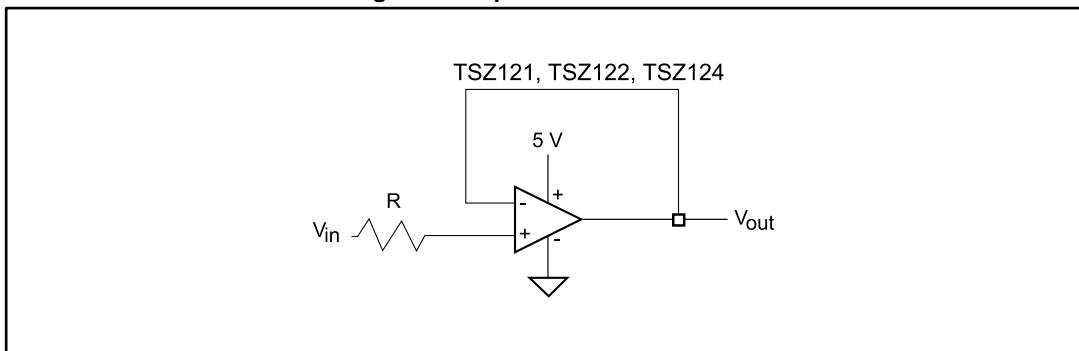

## 5.3 Input pin voltage ranges

TSZ121, TSZ122, and TSZ124 devices have internal ESD diode protection on the inputs. These diodes are connected between the input and each supply rail to protect the input MOSFETs from electrical discharge.

If the input pin voltage exceeds the power supply by 0.5 V, the ESD diodes become conductive and excessive current can flow through them. Without limitation this over current can damage the device.

In this case, it is important to limit the current to 10 mA, by adding resistance on the input pin, as described in [Figure 42: "Input current limitation"](#).

Figure 42: Input current limitation

## 5.4 Rail-to-rail input

TSZ121, TSZ122, and TSZ124 devices have a rail-to-rail input, and the input common mode range is extended from  $(V_{CC-}) - 0.1$  V to  $(V_{CC+}) + 0.1$  V.

## 5.5 Input offset voltage drift over temperature

The maximum input voltage drift variation over temperature is defined as the offset variation related to the offset value measured at 25 °C. The operational amplifier is one of the main circuits of the signal conditioning chain, and the amplifier input offset is a major contributor to the chain accuracy. The signal chain accuracy at 25 °C can be compensated during production at application level. The maximum input voltage drift over temperature enables the system designer to anticipate the effect of temperature variations.

The maximum input voltage drift over temperature is computed using [Equation 1](#).

### Equation 1

$$\frac{\Delta V_{io}}{\Delta T} = \max \left| \frac{V_{io}(T) - V_{io}(25\text{ }^{\circ}\text{C})}{T - 25\text{ }^{\circ}\text{C}} \right|$$

Where T = -40 °C and 125 °C.

The TSZ121, TSZ122, and TSZ124 datasheet maximum value is guaranteed by measurements on a representative sample size ensuring a C<sub>pk</sub> (process capability index) greater than 1.3.

## 5.6 Rail-to-rail output

The operational amplifier output levels can go close to the rails: to a maximum of 30 mV above and below the rail when connected to a 10 kΩ resistive load to V<sub>CC</sub>/2.

## 5.7 Capacitive load

Driving large capacitive loads can cause stability problems. Increasing the load capacitance produces gain peaking in the frequency response, with overshoot and ringing in the step response. It is usually considered that with a gain peaking higher than 2.3 dB an op amp might become unstable.

Generally, the unity gain configuration is the worst case for stability and the ability to drive large capacitive loads.

[Figure 43: "Stability criteria with a serial resistor at VDD = 5 V"](#) and [Figure 44: "Stability criteria with a serial resistor at VDD = 1.8 V"](#) show the serial resistor that must be added to the output, to make a system stable. [Figure 45: "Test configuration for Riso"](#) shows the test configuration using an isolation resistor, Riso.

Figure 43: Stability criteria with a serial resistor at VDD = 5 V

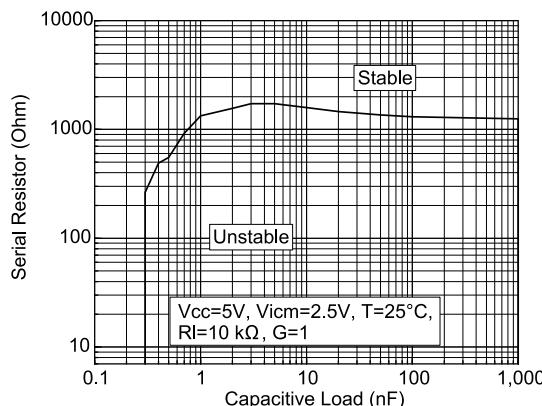

Figure 44: Stability criteria with a serial resistor at VDD = 1.8 V

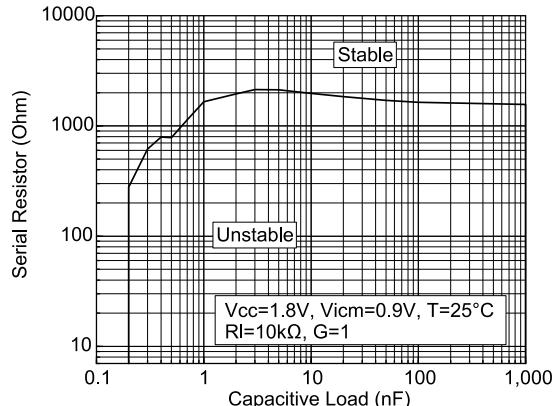

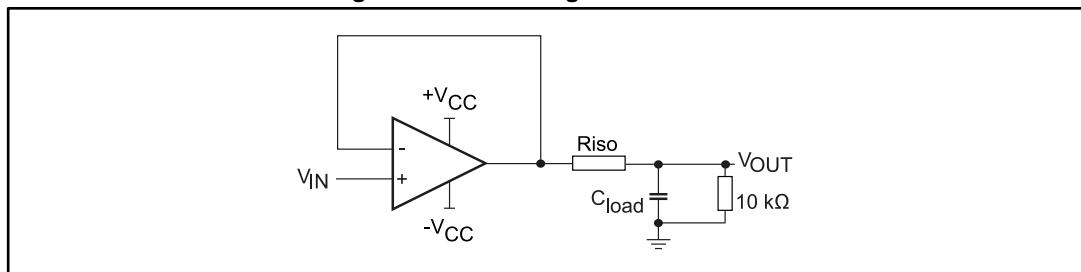

Figure 45: Test configuration for Riso

## 5.8 PCB layout recommendations

Particular attention must be paid to the layout of the PCB, tracks connected to the amplifier, load, and power supply. The power and ground traces are critical as they must provide adequate energy and grounding for all circuits. Good practice is to use short and wide PCB traces to minimize voltage drops and parasitic inductance.

In addition, to minimize parasitic impedance over the entire surface, a multi-via technique that connects the bottom and top layer ground planes together in many locations is often used.

The copper traces that connect the output pins to the load and supply pins should be as wide as possible to minimize trace resistance.

## 5.9 Optimized application recommendation

TSZ121, TSZ122, and TSZ124 devices are based on chopper architecture. As they are switched devices, it is strongly recommended to place a 0.1  $\mu$ F capacitor as close as possible to the supply pins.

A good decoupling has several advantages for an application. First, it helps to reduce electromagnetic interference. Due to the modulation of the chopper, the decoupling capacitance also helps to reject the small ripple that may appear on the output.

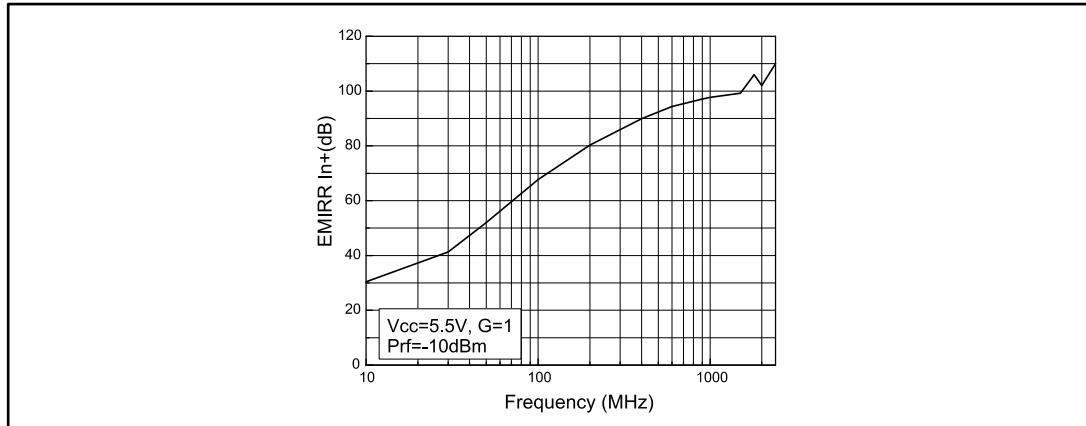

TSZ121, TSZ122, and TSZ124 devices have been optimized for use with 10 kΩ in the feedback loop. With this, or a higher value of resistance, these devices offer the best performance.

## 5.10 EMI rejection ration (EMIRR)

The electromagnetic interference (EMI) rejection ratio, or EMIRR, describes the EMI immunity of operational amplifiers. An adverse effect that is common to many op amps is a change in the offset voltage as a result of RF signal rectification.

The TSZ121, TSZ122, and TSZ124 have been specially designed to minimize susceptibility to EMIRR and show an extremely good sensitivity. [Figure 46: "EMIRR on IN+ pin"](#) shows the EMIRR IN+ of the TSZ121, TSZ122, and TSZ124 measured from 10 MHz up to 2.4 GHz.

**Figure 46: EMIRR on IN+ pin**

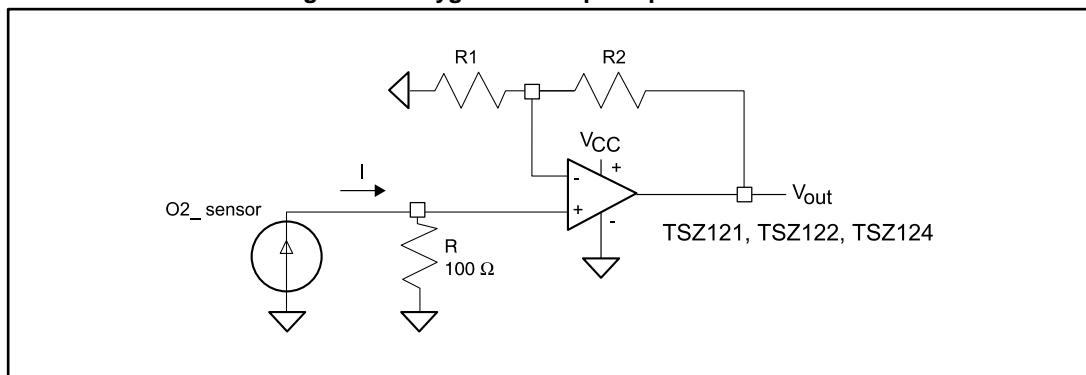

## 5.11 Application examples

### 5.11.1 Oxygen sensor

The electrochemical sensor creates a current proportional to the concentration of the gas being measured. This current is converted into voltage thanks to R resistance. This voltage is then amplified by TSZ121, TSZ122, and TSZ124 devices (see [Figure 47: "Oxygen sensor principle schematic"](#)).

**Figure 47: Oxygen sensor principle schematic**

The output voltage is calculated using [Equation 2](#):

### Equation 2

$$V_{\text{out}} = (I \times R - V_{\text{io}}) \times \left( \frac{R_2}{R_1} + 1 \right)$$

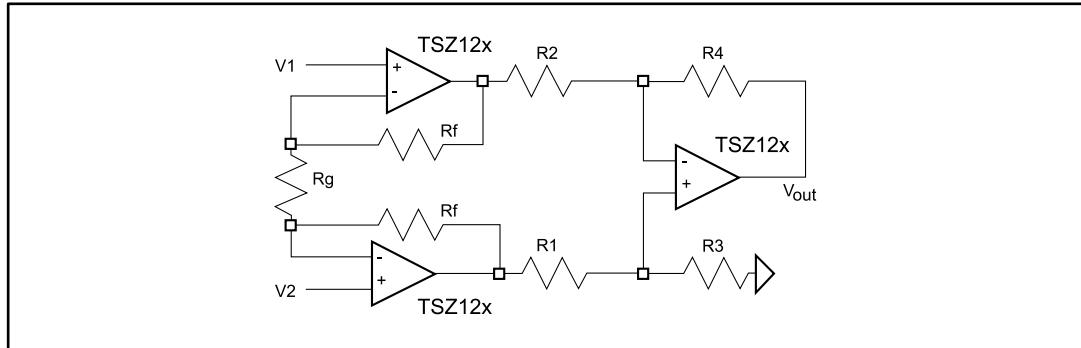

As the current delivered by the O<sub>2</sub> sensor is extremely low, the impact of the  $V_{\text{io}}$  can become significant with a traditional operational amplifier. The use of the chopper amplifier of the TSZ121, TSZ122, or TSZ124 is perfect for this application.

In addition, using TSZ121, TSZ122, or TSZ124 devices for the O<sub>2</sub> sensor application ensures that the measurement of O<sub>2</sub> concentration is stable even at different temperature thanks to a very good  $\Delta V_{\text{io}}/\Delta T$ .

## 5.11.2 Precision instrumentation amplifier

The instrumentation amplifier uses three op amps. The circuit, shown in [Figure 48: "Precision instrumentation amplifier schematic"](#), exhibits high input impedance, so that the source impedance of the connected sensor has no impact on the amplification.

**Figure 48: Precision instrumentation amplifier schematic**

The gain is set by tuning the  $R_g$  resistor. With  $R_1 = R_2$  and  $R_3 = R_4$ , the output is given by [Equation 3](#).

### Equation 3

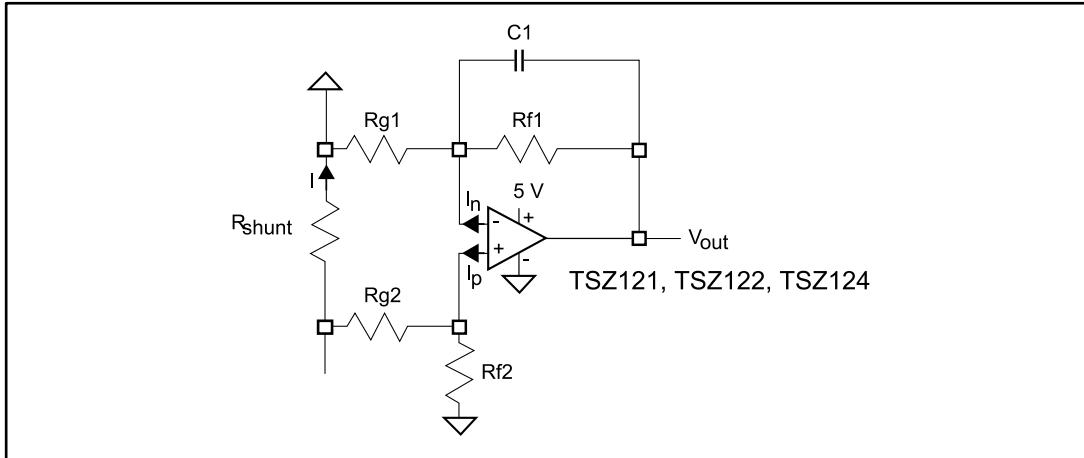

$$V_{\text{out}} = (V_2 - V_1) \left[ \frac{R_4}{R_2} \cdot \frac{2R_f}{R_g} + 1 \right]$$

The matching of  $R_1$ ,  $R_2$  and  $R_3$ ,  $R_4$  is important to ensure a good common mode rejection ratio (CMR).

### 5.11.3 Low-side current sensing

Power management mechanisms are found in most electronic systems. Current sensing is useful for protecting applications. The low-side current sensing method consists of placing a sense resistor between the load and the circuit ground. The resulting voltage drop is amplified using TSZ121, TSZ122, and TSZ124 devices (see [Figure 49: "Low-side current sensing schematic"](#)).

**Figure 49: Low-side current sensing schematic**

$V_{out}$  can be expressed as follows:

**Equation 4**

$$V_{out} = R_{shunt} \times I \left( 1 - \frac{R_{g2}}{R_{g2} + R_{f2}} \right) \left( 1 + \frac{R_{f1}}{R_{g1}} \right) + I_p \left( \frac{R_{g2} \times R_{f2}}{R_{g2} + R_{f2}} \right) \times \left( 1 + \frac{R_{f1}}{R_{g1}} \right) - I_n \times R_{f1} - V_{io} \left( 1 + \frac{R_{f1}}{R_{g1}} \right)$$

Assuming that  $R_{f2} = R_{f1} = R_f$  and  $R_{g2} = R_{g1} = R_g$ , [Equation 4](#) can be simplified as follows:

**Equation 5**

$$V_{out} = R_{shunt} \times I \left( \frac{R_f}{R_g} \right) - V_{io} \left( 1 + \frac{R_f}{R_g} \right) + R_f \times I_{io}$$

The main advantage of using the chopper of the TSZ121, TSZ122, and TSZ124, for a low-side current sensing, is that the errors due to  $V_{io}$  and  $I_{io}$  are extremely low and may be neglected.

Therefore, for the same accuracy, the shunt resistor can be chosen with a lower value, resulting in lower power dissipation, lower drop in the ground path, and lower cost.

Particular attention must be paid on the matching and precision of  $R_{g1}$ ,  $R_{g2}$ ,  $R_{f1}$ , and  $R_{f2}$ , to maximize the accuracy of the measurement.

## 6 Package information

In order to meet environmental requirements, ST offers these devices in different grades of ECOPACK® packages, depending on their level of environmental compliance. ECOPACK® specifications, grade definitions and product status are available at: [www.st.com](http://www.st.com).  
ECOPACK® is an ST trademark.
