TOSHIBA BIPOLAR LINEAR INTEGRATED CIRCUIT

SILICON MONOLITHIC

**FM IF SYSTEM (DIFFERENTIAL PEAK DETECTION)**

TA8129Z, an IC designed for car tuner, has a flexible muting function and a station detection function leading to make it possible to realize the feature appropriate to the specification of the car tuner.

- . Differential 6-stage IF Limiter
- . Signal Meter Output
- . Differential Peak Detection
- . Station Detection
- . Bandwidth Muting
- . Signal Strength Muting

**ZIP16-P**

Weight: ZIP16-P: 0.99g (Typ.)

- . Application of differential peak detection is useful against multi-path distortion.
- . With single tuned coil, low distortion ratio can be realized. (0.05%, typical at 75kHz dev.)
- . Sensitivity of signal strength muting, sensitivity of attenuation and stop signal, and bandwidth can freely be set with external resistance.
- . Signal meter output proportioned to input signal strength can be obtained.
- . AMR is excellent. (55dB, typical at  $V_i=80\text{dB}\mu$ )
- . S/N is excellent. (78dB, typical.)
- . S curve variation against input voltage is made reduced. ( $\pm 100\text{mV}$ , typical at  $V_i=0\sim 120\text{dB}\mu$ )
- . Operating Power Supply Voltage :  $V_{opr}=7\sim 16\text{V}$  ( $T_a=25^\circ\text{C}$ )

**MAXIMUM RATINGS ( $T_a=25^\circ\text{C}$ )**

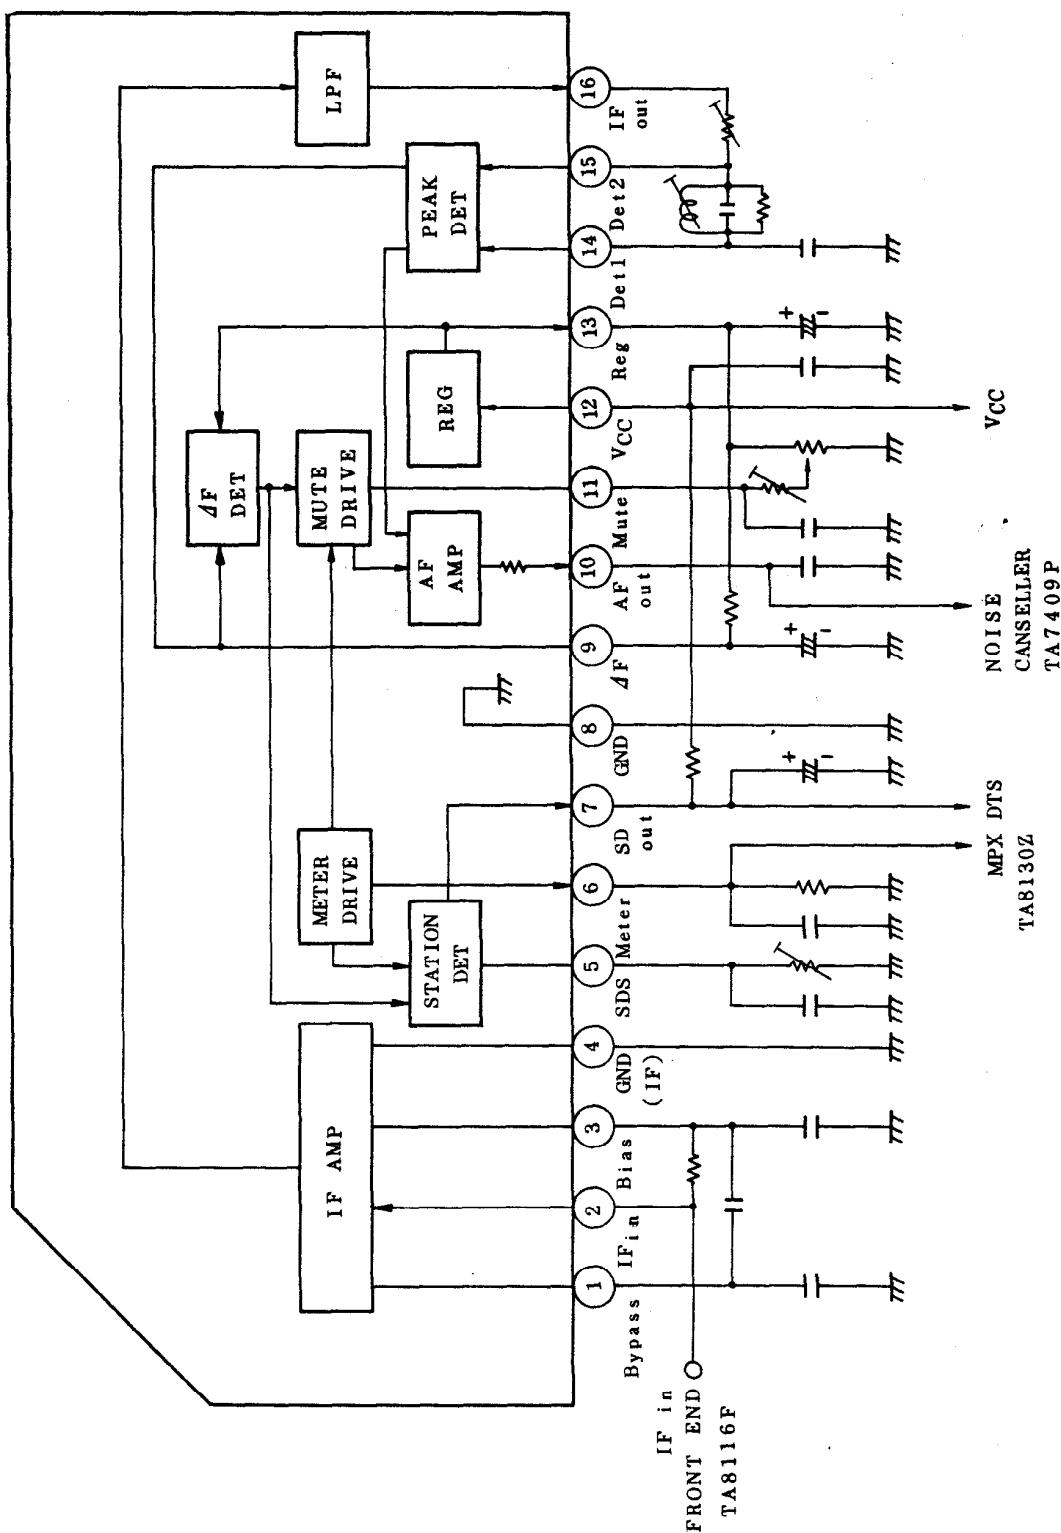

CHARACTERISTIC	SYMBOL	RATING	UNIT
Power Supply Voltage	$V_{CC}$	16	V
Power Dissipation	$P_D$	750	mW
Operating Temperature	$T_{opr}$	-30~85	$^\circ\text{C}$
Storage Temperature	$T_{stg}$	-55~150	$^\circ\text{C}$
Tuning Indication Current	$I_{17\text{ MAX.}}$	20	mA
External Leak Current	$I_{113\text{ MAX.}}$	5	mA

Note. Derated above  $25^\circ\text{C}$  in the proportion of  $6\text{mW}/^\circ\text{C}$ .

## DIFFERENTIAL DETECTION

The differential peak detection system means a system for detecting the variation of voltages of  $e_1$  and  $e_2$  when the input frequency is varied and amplified the DC voltage by a differential amplifier to take out the detection output.

In figure 2, the level of  $e_1$  and  $e_2$  for the input frequency is shown, the point where  $e_1$  becomes minimum is the point where the impedance  $Z$  viewed from the point  $e_1$  becomes minimum and the impedance  $Z_1$  is expressed by the following equation,

$$Z_1 = \frac{1+S^2 L(C_1+C_2)}{S C^2 (1+S^2 L C_1)} \dots \quad (1)$$

(Where,  $S=j\omega$ )

and  $f_L$  is expressed by the equation (2).

$$f_L = \frac{1}{2\pi\sqrt{L(C_1+C_2)}} \dots \quad (2)$$

Also, the point where  $e_2$  becomes minimum is the point where  $L$  and  $C_1$  are oscillated in parallel, and  $f_H$  is expressed by the equation (3).

$$f_H = \frac{1}{2\pi\sqrt{L C_1}} \dots \quad (3)$$

Further, the inductive susceptance of  $L$  and  $C_1$  becomes  $f_0$  when it becomes 1/2 of the capacitive susceptance of  $C_2$ , and the  $f_0$  is expressed by the equation (4).

$$f_0 = \frac{1}{2\pi\sqrt{L(C_1+C_2/2)}} \dots \quad (4)$$

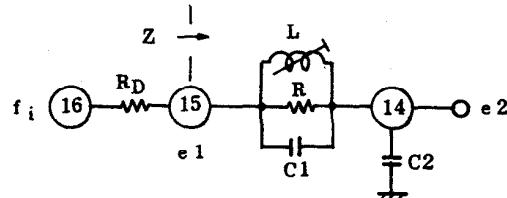

Fig. 1

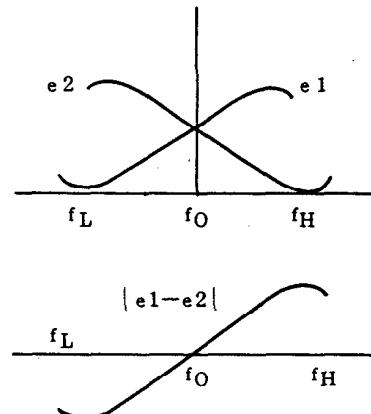

Fig. 2

**TOSHIBA****INTEGRATED CIRCUIT**

TECHNICAL DATA

**TA8129Z**

The detection output is determined by the width of  $f_H - f_L$ , that is, it is proportional to the ratio ( $C_1/C_2$ ) of  $C_1$  and  $C_2$ . Figure 3 shows the variation of the detection output of  $C_1=24\text{pF}$  to  $C_2$ . It is necessary to pay attention that when the detection output is reduced by decreasing  $C_1/C_2$ , the detection band is widened and S/N is somewhat lowered, therefore, for reducing the detection output holding a high S/N, and  $R_D$  to adjust the output.

In a conventional quadrature detection, a double tuning coil is required for obtaining a low distortion factor, but as the result, the cost is increased and adjustment is troublesome (it is fairly difficult to make  $f_0$  coincide with the minimum value of distortion).

In the TA8129Z,  $f_0$  adjustment can be performed by coil and distortion adjustment by  $R_D$ , and cost can be reduced and the adjustment time can be shortened.

When making  $R_D$  a fixed resistance,  $R_D=1.2\text{k}\Omega$  is typical for the minimum value of distortion (under the condition of measuring circuit).

As described above, the linearity (distortion) of S curve is determined by the  $R_D$  value. However, on the other hand, it is necessary to vary the  $R_D$  value so as to obtain the minimum value of distortion by the value of  $C_1$  and  $C_2$  and especially,  $C_2$  is most influenced.

Set  $R_2$  for  $C_1$  and  $C_2$  by referring to the graph in Figure 3.

## SIGNAL INTENSITY MUTING PROPERTIES

The muting circuit of the TA8129Z is constituted of an AF amplifier where gain is varied by control voltage and a control voltage generation circuit (Mute Drive) proportional to a signal meter output.

Figure 4 shows the outline of the muting circuit. The signal meter output is converted into the current by  $10k\Omega$  externally provided on 6 pin and  $\frac{1}{3} I$  current is output in 11 pin in 1:1/3 current mirror circuit. This current is converted into a control voltage by RMS and VH connected outside.

The attenuation amount at non-signal is substantially determined by the value of VH since the current output in 11 pin is about 0. The VH is set by the output of the volume RMD of about  $10k\Omega$  connected to the constant voltage output (13 pin) of 4.8V. The variation ratio (gradient) of attenuation amount of a detection output is determined by the ratio of the variation of the 11 pin voltage VMD to the level of an input signal, that is the variation of the signal meter voltage.

Accordingly, as RMS becomes larger, the gradient becomes steep. It is presumed that usually, the value of RMS is preferably about  $33k\Omega$ .

- Attenuation amount at non-input → Adjust by RMD
- Limiting adjustment → Adjust by RMS

Fig. 4

### MUTING PROPERTIES FOR DETUNING

In the 9 pin of AFC terminal,  $\pm$  currents proportional to the S curve are generated. The AC component of them is smoothed by an external capacity and a DC voltage is generated in 9 pin by RBW connected between 9 pin and 13 pin. When the DC voltage generated by RBW becomes over about  $\pm 0.7V$ , the detection circuit ( $\Delta f$  Det) is operated to attenuate the AF amplifier by about 40dB.

The width of muting for detuning is determined by the resistance value of RBW, but the coil previously described is varied by setting, and set the value of RBW after setting of the coil.

The property when varying RBW on the condition of the measuring circuit is shown in Figure 5.

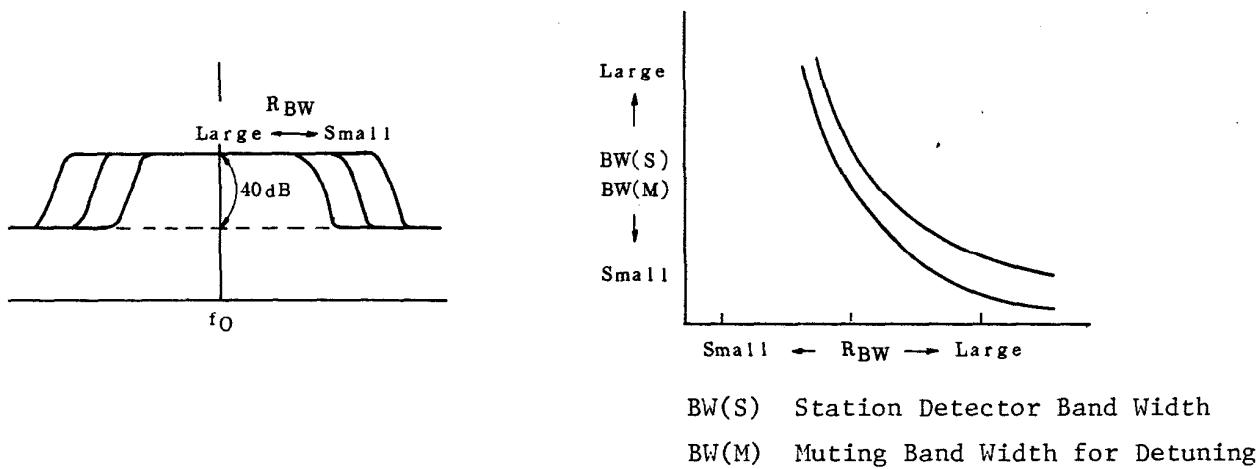

Fig. 5

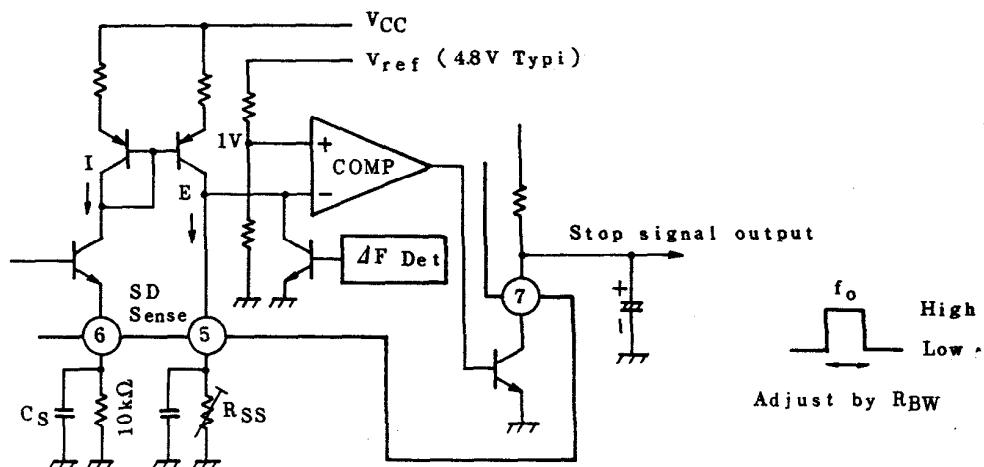

### STATION DETECTOR

The station detector (stop signal generator of DTS) detects detuning by the signal intensitly of input and  $\Delta f$  detection circuit ( $\Delta f$  Det) respectively and outputs through AND circuit.

As shown in Figure 6, the signal meter output is converted into the current I by the  $10k\Omega$  connected to 6 pin and outputs the current I in 5 pin by a current mittor circuit.

This current is converted to -input of the comparator where 1V is added to +input. Therefore, the stop signal sensitivity can be adjusted by varying the value of the RSS connected to 5 pin.

Also, the variable width of the stop signal sensitivity is set widely as about 40dB $\mu$  by IF input voltage (when RSS=2k $\Omega$ ~10k $\Omega$ ). The band width is varied by RBW shown in Figure 5.

#### ADJUSTMENT METHOD OF TA8129Z

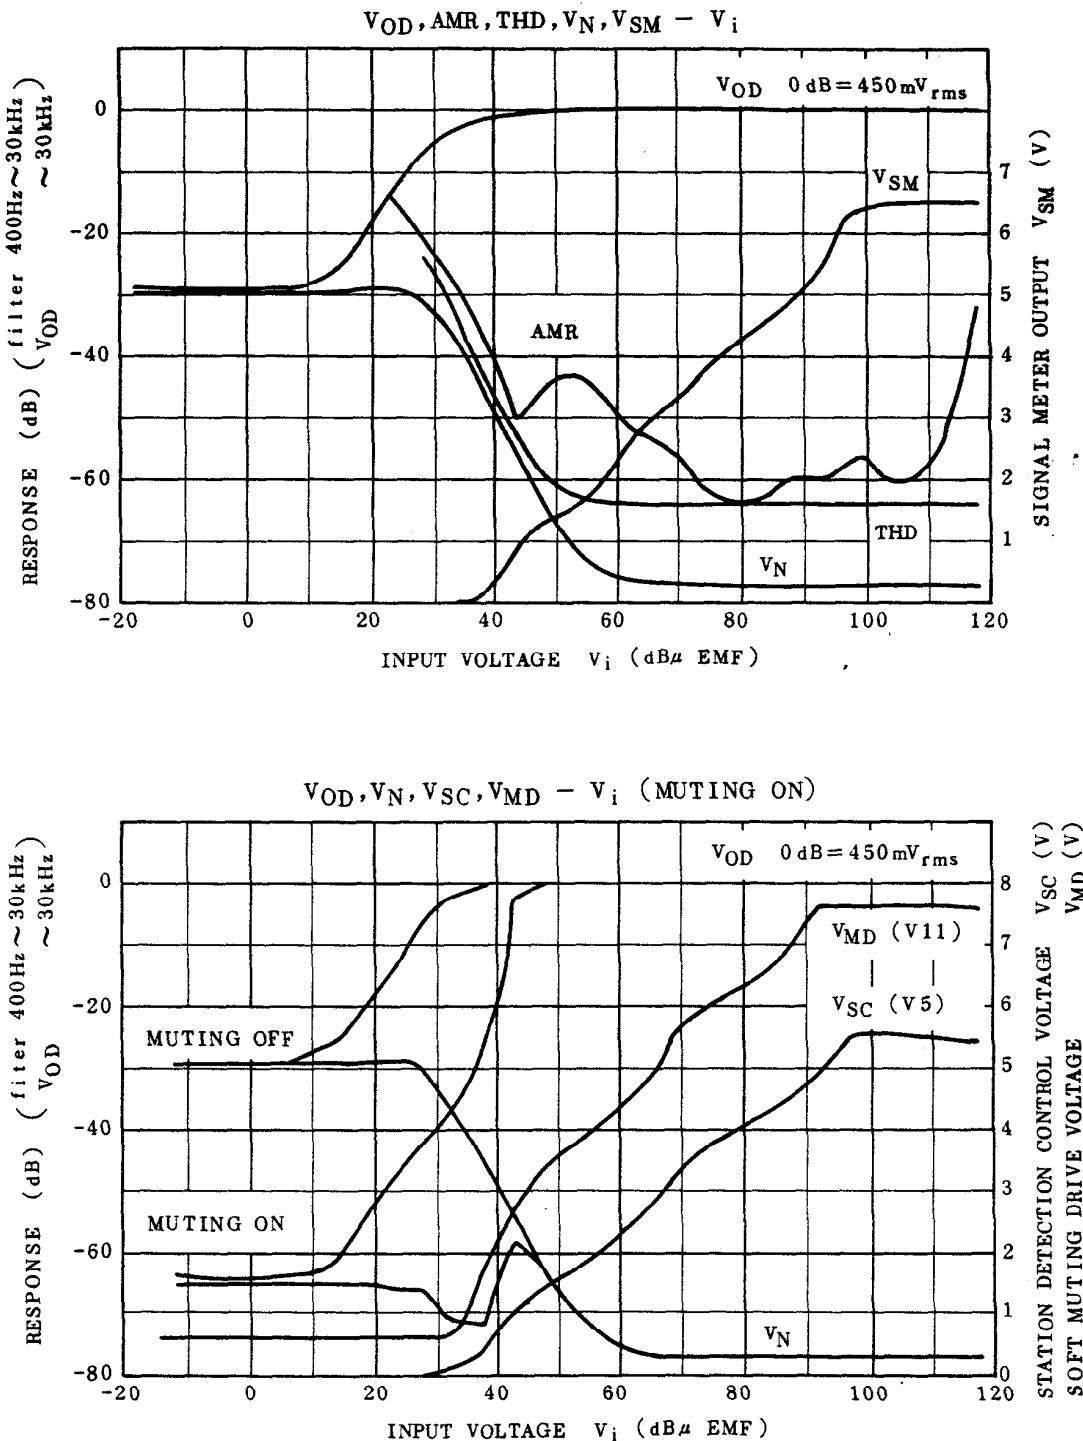

- Apply the signal of 10.7MHz, 80dB $\mu$  to input.
- Connect a voltmeter between 9 pin and 13 pin.
- Adjust T1 and set the indication of the voltmeter to about 0V.
- Adjust RD so that the detection distortion becomes minimum.  
(When RD is a variable resistance.)

#### PRECAUTION

- When the capacity value of the by-pass capacitor CS connected to 6 pin of meter output is fairly large, the audio signal corresponding to AM wave flows and the AMR properties are deteriorated. Use at under 0.01μF.
